
Points: RMSE ratios; bars: 90% moving-block bootstrap intervals. e: quarters from the indicator's latest data. Primary test: survey at h = 1.
Coverage note: in simulations with the real indicator paths, these 90% intervals contained the true ratio in 83–100% of replications when the indicator had an effect.
With no effect, they contained 1 in only 79–83% (survey) and 67–73% (credit) of replications; almost all misses lay wholly above 1, reflecting estimation cost.
A credible improvement with no effect occurred in at most 3% of replications.
