Real-Time Credit Impulse Project: Red-Team Review & Preregistration Protocol

Oct 17, 2026 · @Andy

Decision, 17 Oct 2026: scope narrowed to one question: *did US private credit flows carry information about output and unemployment that a forecaster could have used at the time, 1990–2019?* The DSGE horse race is dropped because it has already been run on real-time data (Edge–Gürkaynak; Del Negro–Schorfheide; Wieland–Wolters). Protocol v2.3 below replaces all earlier versions. The red-team findings stay as the rationale.

Summary verdict

The plan is sound in spirit but not yet lockable: five design flaws would let the results say more than the data can support. The factual premises check out; the framing of what is being tested does not.

What holds

- The 2026 prize to Robert E. Hall and Michael Woodford "for microeconomic foundations of macroeconomic stabilisation" is confirmed (announced 12 October 2026).
- NBER WP 35875 (Freeman, Xie, Zhang & Zhou) exists and says what the plan says it says.
- Real-time US data for GDP, inflation, unemployment and the policy rate exist and are well documented.
- The "simplest model first" ladder is good practice and matches the forecasting literature's own benchmarks.

What breaks (must fix before lock)

1. **Construct validity.** The prize claims better *policy design*, not better *forecasts*. Forecast accuracy is a fair but partial test. H1 must be restated as a forecasting claim, not a verdict on the prize.
2. **The 2007–09 window is the discovery sample for H2.** The "credit impulse" was coined in November 2008 and Keen's "credit accelerator" was named around 2010–11. Testing them on the crisis that inspired them is in-sample, however careful the vintages.
3. **Credit data were not available in this form in real time.** The BIS total-credit series launched in March 2013 and is break-adjusted ex post. A real-time credit series must be rebuilt from archived Z.1 releases.

4. **The decision gate makes H1 untestable.** DSGE (Level 3) is reached only if credit-augmented models win. If they lose, H1 is never tested. Use published real-time DSGE forecasts as an unconditional comparator instead.
5. **No statistical power on the primary window.** About 12–16 forecast origins and 3–4 recessions cannot support significance claims. Turning-point results must be pre-declared as descriptive.

Biggest single change: make the full 1990–2019 real-time evaluation the confirmatory test, treat named crisis windows as pre-specified subsets, and treat 2007–09 as exploratory for H2.

Premise verification

All three factual premises are confirmed, but premise 1 needs re-wording so the project tests what the prize actually claims.

Premise in draft	Status	What the record shows	Change needed
2026 Nobel to Hall and Woodford for "microeconomic foundations of macroeconomic stabilisation"	Confirmed	Announced 12 Oct 2026 by the Royal Swedish Academy (press release). Committee says their models improved our ability to implement stabilisation policy and underpin models used by central banks.	Quote the citation exactly. Read the Academy's scientific background PDF before lock and list which specific papers it credits.

Premise in draft	Status	What the record shows	Change needed
Prize ratifies "the NK/DSGE paradigm"	Partly	The prize credits two people's work, not the Smets–Wouters model. Hall's record is broad: his 1978 consumption paper implies a random-walk benchmark; he chaired the NBER Business Cycle Dating Committee for 30+ years (NBER). Woodford's *Interest and Prices* (2003) is the NK core (PUP).	Call it "the NK/DSGE model class descended from this work". Do not attribute Smets–Wouters results to the laureates personally.
NBER WP 35875 documents high and rising concentration	Confirmed	Economics is the only one of 18 fields where prizewinner concentration is rising (NBER w35875).	Keep as motivation only. It is evidence about sociology of prizes, not about model accuracy; say so.
Keen as source of testable debt hypotheses	Confirmed, with caveat	Keen defines the credit accelerator as the change in the change in debt over a year, divided by GDP, and credits Biggs et al. for the idea (Keen 2011).	Cite Biggs, Mayer & Pick (2010) as the operational source; Keen as the theoretical motivation.

Construct-validity note. Forecast accuracy is not the prize's stated contribution. Edge and Gürkaynak argue that, under good monetary policy, a correct NK model itself predicts that inflation deviations are hard to forecast (FEDS 2011-11). So a DSGE that forecasts no better than a random walk is not, by itself, a refutation. The protocol should say this up front, then test anyway: forecasting at turning points is still a necessary condition for policy usefulness in real time.

Conflict-of-definition note. Recession dates come from the NBER committee Hall chaired. This is not bias, but turning-point scoring must use dates *as announced*, and announcement lags (about a year) mean those dates were never available to a real-time

forecaster.

Red-team findings

Each finding names the flaw, why it matters, and the fix written into the protocol below. Severity: **Critical** = would invalidate a headline claim; **Major** = would bias a comparison; **Minor** = reporting hygiene.

1. Forecast target definitions (Major)

- **Undefined growth concept.** "Real GDP growth at h=4" can mean the single quarter four steps ahead (q/q annualised) or cumulative growth over four quarters. They have very different error variances and different winners. *Fix:* primary = q/q annualised at h = 1, 2, 4; secondary = cumulative 4-quarter growth.
- **Undefined "truth".** GDP is revised for years; the 2009 and 2013 comprehensive revisions moved history materially. *Fix:* primary actual = the estimate in the vintage published two quarters after the target quarter ("second-ish release"); robustness = first release and latest vintage. Never mix.
- **Unemployment level vs change.** A random walk in levels is nearly unbeatable at h=1. *Fix:* forecast the quarterly-average level; score RMSE on the level and directional accuracy on the change.
- **Inflation measure unstated.** *Fix:* GDP deflator (matches the DSGE literature's observable), q/q annualised.
- **Turning-point metric undefined.** *Fix:* a pre-written rule, e.g. a model "calls" a recession when its forecast path has two consecutive negative q/q growth quarters or a +0.5 pp rise in unemployment within 4 quarters. Score hits, misses, false alarms and lead time.

2. Real-time vintages (Critical)

- **Credit is the weak link.** The BIS total-credit database was introduced in March 2013 (BIS QR) and its US series is break-adjusted with BIS's own statistical techniques (FRED notes). Neither existed in 2007. *Fix:* build real-time credit from archived Z.1 releases (Fed release archive and FRASER); use BIS only as a final-vintage robustness check.
- **ALFRED coverage of Z.1 looks thin before 2013.** ALFRED vintages for at least some Z.1 series begin in June 2013 (ALFRED Z.1 search). *Fix:* a data-audit step before lock confirms, series by series, the earliest usable vintage; anything missing is reconstructed or the variable is dropped.

- **Release timing.** Z.1 lags quarter-end by about 10 weeks, longer than the GDP advance estimate. *Fix:* the information set at each origin is defined by publication date, not by reference quarter. A ragged edge is allowed and documented.
- **Policy rate at the zero lower bound.** From December 2008 the fed funds rate stops carrying information, which breaks linear VARs. Shadow rates (e.g. Wu–Xia) are estimated ex post and leak. *Fix:* replace fed funds with the 2-year Treasury yield, available unrevised in real time.

3. Crisis-window leakage (Critical)

Leakage here is anything known after a forecast origin that shapes the forecast. Six channels exist:

1. **Hypothesis leakage.** The credit impulse was introduced in a Deutsche Bank note of 19 Nov 2008 (CASE); Keen renamed it in 2011. Both were shaped by watching 2008.
2. **Model-choice leakage.** DSGEs with financial frictions were adopted *because* of the crisis; Del Negro, Hasegawa and Schorfheide note macroeconomists paid little attention to them beforehand (NY Fed SR 695).
3. **Data-construction leakage.** Break adjustment, HP-filtered credit gaps and seasonal factors are computed using later data.
4. **Hyperparameter leakage.** BVAR prior tightness, lag length or rolling-window length tuned on the full sample.
5. **Date leakage.** NBER peak/trough dates used to define windows or to time a forecast.
6. **Researcher leakage.** The analyst knows the outcome. Every specification choice is a potential forking path.

Fix: all specifications frozen before any forecast is computed; hashes recorded; 2007–09 labelled exploratory for H2; confirmatory H2 evidence must come from 1990–91, 2001, and the non-recession years; one-sided filters only; window boundaries set by calendar, not NBER dates.

4. Model comparability (Major)

- **Unequal information sets.** Smets–Wouters uses seven observables; Level 1A uses four. A DSGE "win" may just be more data. *Fix:* report a BVAR on the same seven observables as the DSGE's fair benchmark.
- **Nested models.** 1B nests 1A. The Diebold–Mariano test is invalid for nested comparisons. *Fix:* Clark–West test for 1A vs 1B.
- **Estimation scheme.** *Fix:* expanding window from 1965Q1 for all models, re-estimated at every origin, with a fixed-length rolling window (60 quarters) as robustness.
- **Multi-step method.** *Fix:* iterated forecasts for VAR/AR; direct forecasts as robustness.

- **Trailing mean unspecified ("8 or 12").** *Fix:* lock 8 quarters; 12 as robustness.
- **Do not build your own DSGE first.** Real-time SW and SW-with-financial-frictions forecasts already exist (Del Negro & Schorfheide 2013; Cai et al.) and Wieland–Wolters published real-time model forecasts around five NBER recessions using the Macroeconomic Model Data Base (Wieland & Wolters). Use these as the Level 3 comparator; replicate one only if the archive allows exact alignment.
- **Missing professional benchmarks.** SPF and Greenbook forecasts are the natural human comparators and are already used in this literature. *Fix:* add both as reference rows (not competitors to be beaten).

5. Credit impulse construction (Major)

The draft names "credit impulse" but not its formula. Small definitional choices change the series sign around turning points.

- **Canonical definition.** Biggs, Mayer & Pick: the change in the *flow* of credit relative to GDP (VoxEU). Lock it as:

```
CI_t = \frac{(D_t - D_{t-4}) - (D_{t-4} - D_{t-8})}{\sum_{j=0}^{3} Y_{t-j}}
\times 100
```

where D is end-quarter private non-financial credit and Y is nominal GDP (quarterly, not annualised), both from the same vintage.

- **Levels vs flows.** Z.1 level differences include reclassifications and valuation breaks; Z.1 flow tables exclude them. *Fix:* primary = sum of Z.1 seasonally adjusted flows; robustness = level differences.
- **Revision amplification.** A double difference amplifies revision noise. *Fix:* report the revision variance of CI (first vs latest vintage) before any forecasting.
- **Credit-to-GDP gap.** If used, one-sided HP filter only (BIS uses λ = 400,000). Two-sided filtering is leakage.
- **Quarterly vs annual impulse.** *Fix:* lock the 4-quarter version above; the quarterly double difference is robustness only.
- **Sector scope.** *Fix:* households + non-financial business (Z.1 domestic non-financial excluding government).

6. Sample size and power (Critical)

- **Primary window too small.** 2007Q1–2010Q4 gives 16 origins; at h=4 the overlapping errors leave roughly 4 independent observations. No test has useful power at that size.
- **Turning points are rare.** 1990–2019 holds three US recessions. Hit-rate comparisons on n=3 are anecdotes.

- **Multiple comparisons.** Roughly 10 models × 3 horizons × 3 targets × 4 metrics × 3 windows = 1,080 cells.
- *Fix:* (a) confirmatory sample = all origins 1990Q1–2019Q4 (120 origins); (b) two pre-named primary contrasts only; (c) small-sample corrections (Harvey–Leybourne–Newbold) and fixed-b HAC; (d) Giacomini–Rossi fluctuation test for time-varying performance; (e) Holm correction across primary contrasts; (f) crisis windows and turning points reported descriptively with bootstrap intervals; (g) a pre-lock power simulation stating the minimum detectable RMSE ratio.

7. Decision gate (Critical)

The gate tests H2 and then uses the result to decide whether H1 is tested at all. If 1B fails, DSGE is never evaluated, and H1 silently drops out. It also invites "keep adding complexity until something wins". *Fix:* the gate governs only whether *you build* new models. Evaluation of existing real-time DSGE forecasts is unconditional. Level 2 is dropped from the confirmatory plan.

8. Euro-area extension (Minor)

The ECB's real-time database exists, but the euro-area 2008–13 episode includes a sovereign crisis no US-trained specification anticipates. *Fix:* keep it exploratory and say so; specify it in a separate, later preregistration.

Data availability audit

Every macro series is available in true real time except private credit, which must be reconstructed. Rows marked *verify* are checks to complete and record before lock.

Series	Primary source	Real-time vintages?	Revision risk	Action before lock
Real GDP (ROUTPUT)	Philadelphia Fed RTDSM	Yes, mid-quarter vintages back to 1965	High; benchmark revisions 2009, 2013	Lock vintage-timing rule and "truth" vintage
GDP deflator (P)	RTDSM	Yes	Moderate	Lock as inflation measure
Unemployment rate (RUC)	RTDSM (monthly)	Yes	Low; seasonal factors only	Lock quarterly-average rule

Series	Primary source	Real-time vintages?	Revision risk	Action before lock
Nominal GDP (NOUTPUT)	RTDSM	Yes	High	Needed as credit-impulse denominator, same vintage
2-year Treasury yield	Fed H.15 / FRED	Not revised	None	Replaces fed funds after ZLB
Fed funds rate	FRED	Not revised	None	Keep pre-2008 only, or drop
Private non-financial credit	Fed Z.1 archive + FRASER	Partial; must be reconstructed. ALFRED Z.1 vintages appear to start mid-2013	High; reclassifications	*Verify* earliest machine-readable vintage per series; document gaps
BIS total credit, US	BIS / FRED	No; database launched March 2013, break-adjusted	Not applicable	Final-vintage robustness only
Baa–10y spread	FRED	Not revised	None	Optional observable; needed if comparing to SW-FF
SPF forecasts	Philadelphia Fed SPF	Yes, by construction	None	Reference benchmark
Greenbook forecasts	Philadelphia Fed (released with a lag)	Yes	None	*Verify* coverage through 2019
Real-time DSGE forecasts	Del Negro & Schorfheide (2013); Cai et al.; Wieland–Wolters / MMB	Published, real-time or pseudo-real-time	Mixed	*Verify* which are "real real-time" vs reconstructed; label each

Series	Primary source	Real-time vintages?	Revision risk	Action before lock
NBER cycle dates + announcement dates	NBER	Announcement dates known	None	Use for scoring only, never as model input

Two caveats apply to the published DSGE forecasts. Edge et al. note their own "real-time" forecasts were produced retrospectively (FEDS 2009-10), and model choice may still embed hindsight. Label every comparator as *real real-time* (made at the time) or *pseudo real-time* (made later on old vintages).

Preregistration checklist

Tick every box before computing a single forecast error. Anything unticked at lock is either resolved or explicitly listed as a deviation.

A. Claims and framing

- ☐ Nobel framing reduced to one sentence of motivation; no claim about the prize or DSGE models
- ☐ Construct-validity caveat (forecasting ≠ policy design) written into the protocol
- ☐ Exact Nobel citation quoted; Academy scientific background read and credited papers listed
- ☐ Primary contrasts named (max two) and all others labelled secondary or exploratory
- ☐ 2007–09 labelled exploratory for H2, with reason (hypothesis formed on that episode)

B. Targets and truth

- ☐ Growth concept locked (q/q annualised primary; 4Q cumulative secondary)
- ☐ Inflation measure locked (GDP deflator)
- ☐ Unemployment target locked (quarterly-average level; direction scored on change)
- ☐ "Truth" vintage rule locked (published two quarters after target; first release and latest as robustness)
- ☐ Turning-point call rule written down, with lead-time scoring

C. Data and vintages

- ☐ Series IDs, sources and transformations listed in a data dictionary
- ☐ Forecast-origin timing rule locked (mid-quarter, matching RTDSM)
- ☐ Information set defined by publication date, ragged edge documented
- ☐ Z.1 vintage audit complete: earliest usable vintage per credit series recorded

- [ ] Policy-rate variable locked (2-year yield)
- [ ] Raw vintage files archived with SHA-256 hashes

D. Credit variables

- [ ] Credit-impulse formula locked (4-quarter version, flows-based, same-vintage nominal GDP)
- [ ] Sector scope locked (households + non-financial business)
- [ ] Any gap measure uses a one-sided filter only
- [ ] Revision-variance diagnostic of CI scheduled before forecasting

E. Models

- [ ] Level 0 locked: random walk, 8-quarter trailing mean, AR(1), AR(2)
- [ ] Level 1A/1B locked: variables, lag length (fixed at 2), BVAR prior and hyperparameters fixed in advance
- [ ] Estimation scheme locked (expanding from 1965Q1; 60-quarter rolling as robustness)
- [ ] Iterated multi-step for VAR/AR locked
- [ ] ADL model (AR(2) + credit impulse) locked as the simplest credit test
- [ ] Latest-vintage credit series built for the hindsight comparison (H-C)
- [ ] SPF and Greenbook added as reference rows
- [ ] Phase 0 go/no-go rule and sample fallback recorded

F. Evaluation and inference

- [ ] Confirmatory sample locked: origins 1990Q1–2019Q4
- [ ] Crisis windows fixed by calendar quarters, not NBER dates
- [ ] COVID (2020–21) excluded from confirmatory sample; reported separately
- [ ] Tests locked: Clark–West for nested, DM with HLN correction for non-nested, Giacomini–Rossi fluctuation test
- [ ] Multiple-comparison rule locked (Holm across primary contrasts)
- [ ] Power simulation run; minimum detectable RMSE ratio stated
- [ ] Inference language rule: no significance claims on crisis windows or turning points

G. Process

- [ ] Protocol committed to a public timestamped repository (e.g. OSF or tagged GitHub release) before analysis
- [ ] Code for all models written and run on synthetic data only before lock
- [ ] Deviation log created; every post-lock change dated and justified
- [ ] All results reported, including failures and null findings

H. v2.1 additions

- [ ] "Revised" target vintage frozen (download date recorded)
- [ ] SPF survey deadlines and Z.1 release dates tabulated for every quarter
- [ ] SPF test uses only Z.1 releases published before each survey deadline
- [ ] Three credit measures pre-registered as one family, Holm-corrected within it
- [ ] Credit gap uses a one-sided HP filter (λ = 400,000), recomputed at every vintage
- [ ] Threshold rules have no free parameters; false alarms counted across all quarters
- [ ] GDI vintage coverage checked in ALFRED
- [ ] Nowcasting parked; not run under this protocol

I. v2.2 additions

- [ ] Claim worded as predictive content under real-time vintages; no causal language anywhere
- [ ] Vintage-by-vintage series mapping table complete (table, line, series code per Z.1 vintage)
- [ ] PDF extraction protocol followed for any pre-digital Z.1 vintage; reconciliation log archived
- [ ] Z.1 and GDI release-date tables complete; origins without a known date dropped
- [ ] Realistic power simulation published (actual origins, overlap, Holm across four); conditional rules in §11 applied
- [ ] COVID exclusion applied by target quarter

J. v2.3 additions

- [ ] Interpretive map locked; unlisted patterns to be reported as "unanticipated"
- [ ] Advance-estimate release dates tabulated for P3 anchors
- [ ] Real-time GDP deflator mapped for real credit growth
- [ ] Data vintage of López-Buenache et al. (2025) confirmed with the authors, or stated as an inference
- [ ] CBO natural-rate vintages checked in ALFRED (E1 only)
- [ ] Power simulation extended to P3 and S5

Preregistration protocol v2.3

LOCKED 19 Oct 2026: GitHub release v1.0-lock, commit 4eb084f, DOI 10.5281/zenodo.23477871 (audit Entry 21). This is the locked text; it replaces v2.2. Fields in [brackets] are filled in Phases 0–1, before any forecast is computed. Notation: o = origin quarter; s = target quarter; v = Z.1 vintage; w = GDP vintage.

1. Claim and its limits

Question. Under the data vintages available at each date, did standard credit transformations have predictive content for subsequently revised US real GDP growth and unemployment, 1990–2019? How much of the predictive content measured on revised data depends on revisions to the credit data?

What this does not claim.

- **No causal claim.** The project measures predictive content, not whether credit drives demand.
- **Real-time data is not real-time knowledge.** The credit impulse was first defined in November 2008, and Keen's credit accelerator in 2011. Results before 2008 show what this transformation *would have delivered* applied to contemporaneous data, not what forecasters knew or could reasonably have chosen. Credit growth and credit-to-GDP were standard before 2008, so the horse race in S2 is a partial check on this concept hindsight.
- **P2 is counterfactual.** "Would have improved the SPF" means the information was in published data. It does not mean forecasters erred by ignoring it.
- No claim about DSGE models or the 2026 Economics prize.

Related evidence. López-Buenache, Borsi and Rosa-García (2025) find that credit contractions improve the identification and recursive forecasting of labour-market slack in a Markov-switching framework (US, 1955–2023). Their out-of-sample exercise is recursive from 2000, but the data do not appear to be vintage-based, and slack is defined against an estimated natural rate that is itself revised. The present project tests whether that signal survives a real-time information set and revised-outcome scoring, over an overlapping 2000–2019 window. *Open item:* confirm the data vintage with the corresponding author before citing this as fact.

Closest precedent. Edge and Meisenzahl (2011) show that real-time revisions to the US credit-to-GDP gap are about as large as the gap itself, and come mainly from the filter's unreliable end-of-sample trend rather than from revisions to the underlying data. Their question is **reliability**: does the measure move after the fact? This project asks about **usefulness for macro forecasting**: did the measure, as published, carry information about later output, unemployment, professional forecast errors and GDP revisions? Real-time usefulness tests already exist in the early-warning literature (e.g. Alessi and Detken, 2011), but for crisis prediction, not for macro forecasts or forecaster counterfactuals; the novelty claimed here is scoped to the latter.

What is new relative to them.

- **Window.** The sample runs to 2019 and includes the post-2008 period, when the impulse concept was public (S6). That is the more informative half of the freshness claim.

- **Channel.** The impulse uses no filter, so it isolates the channel they found secondary: data revisions. Two forces pull in opposite directions. Double differencing amplifies revision noise. But S_t is a four-quarter sum of flows, which averages away part of the noise hitting individual quarters, while Z.1 flows are themselves subject to large periodic benchmark revisions. The size of the impulse's revision premium is therefore genuinely open.
- **No pre-commitment to either story.** A measure can be revised heavily and still predict well, if revisions hit parts that do not matter. It can equally lose its predictive content precisely because revisions hit the parts that did. The grid (§2) and interpretive map (§4a) distinguish these cases; neither is assumed.

2. The organising grid

	Early-estimate target	Revised target
Real-time credit vintage	Real-time vintage, early target (reference)	**Primary cell**
Revised credit vintage	Not reported	Revised-data benchmark (as in most published work)

Credit-revision premium = RMSE ratio (credit model ÷ benchmark) using real-time credit and denominator, minus the same ratio using revised credit with the real-time GDP denominator, so that a positive premium means revised credit data forecast better (sign fixed 19 Oct 2026, audit Entry 17). Both are scored against the revised target. It isolates revisions to the credit data, holding the transformation fixed. The **total predictor-revision premium** (revised credit *and* revised denominator) is reported as a secondary decomposition. Neither premium measures concept hindsight; §1 covers that.

3. Phases and go/no-go

Phase 0 — data audit. Each gate is recorded as pass or fail before Phase 1 begins.

Gate	Criterion	If it fails
G1 Credit vintages	A complete vintage-by-vintage mapping table (Z.1 table, line, series code, units, SA status) for every vintage used, and at least 60 consecutive origins with all components present	Project stops at a dataset note

Gate	Criterion	If it fails
G2 Z.1 release dates	Exact publication date verified for every vintage used	Undated vintage dropped; the origin uses the latest earlier dated vintage
G3 GDI vintages	First-release and anchor-date GDI values for at least 60 target quarters	S3 dropped; P3 runs on GDP alone
G4 SPF deadlines	Documented deadline for every survey in the P2 sample (Philadelphia Fed release-dates file; surveys from 1990Q3 only), and at least 40 evaluation surveys after the training period	P2 demoted to secondary

Sample-start decision (17 Oct 2026, before any forecast). The confirmatory sample starts at origin **1999Q3**, the first origin after the June 11, 1999 Z.1 release, which is the earliest vintage with machine-readable full quarterly history. It runs to 2018Q4 at h = 4: 78 origins, which passes G1. Earlier vintages print only the last 4–5 years of quarterly data, so they cannot supply a full real-time estimation history. An **exploratory extension to 1990Q1** uses a hybrid vintage: real-time values for the quarters printed in each PDF release, spliced onto older history from the June 1999 vintage. It is labelled as carrying a partial hindsight leak, and it never enters the confirmatory tests. As a consequence, the 1990–91 recession is exploratory only, and the 2001 and 2007–09 recessions remain in the confirmatory sample.

Mapping table. Z.1 series names and codes changed over time (e.g. "credit market instruments" became "debt securities and loans"). The table links each vintage's series to one consistent concept. Any break in definition is logged with its date, never smoothed.

PDF extraction protocol (any vintage without machine-readable files):

1. Record source URL, file SHA-256 and page numbers for every table used.
2. Extract twice, independently: (a) automated, from the PDF text layer, or OCR (Tesseract) if none; (b) manual keying, blind to (a).
3. Resolve every cell where (a) and (b) differ by inspecting the page image; log each resolution.
4. Check that components sum to printed totals within ±1 in the last printed digit. Flag, but do not force, mismatches between flows and level changes.
5. Record units and seasonal-adjustment status from each table header.
6. Extract only series listed in the mapping table.

Phase 1 builds all credit measures in real-time and revised form, runs the revision study and the power simulation (§11), and draws the raw-series graphs. No forecasts are computed. **Lock** follows, then **Phase 2** runs every test once.

4. Hypotheses and decision rules

ID	Hypothesis	Status	Test
P1a	Real-time credit impulse adds predictive content for revised real GDP growth at h = 4 over AR(2)	**Confirmatory**	Direct ADL vs direct AR(2), Clark–West, one-sided
P1b	Same, for the unemployment rate	**Confirmatory**	As above
P2a	Real-time credit impulse, published before each survey deadline, would have improved bias-corrected SPF median GDP growth forecasts at h = 4	**Confirmatory**	Corrected vs bias-corrected SPF, Clark–West
P3	Real-time credit impulse predicts later revisions to first-release GDP growth	**Confirmatory**	§9; two-sided HAC t-test
P2b	Same as P2a, for SPF unemployment forecasts	Exploratory	As P2a
S1	Credit-revision premium is positive	Exploratory	§2; block bootstrap interval
S2	Ranking of credit impulse, credit growth, credit-to-GDP gap and real credit growth	Exploratory	Each in the P1 model
S3	Real-time credit predicts GDI revisions, and GDP revisions controlling for GDI	Exploratory	Dropped: G3 failed (audit Entry 7)
S4	P1 using the BVAR (1A vs 1B)	Exploratory	§8
S5	Predictive content is concentrated in credit contractions	Exploratory	Asymmetric and contraction ADLs (§8)

ID	Hypothesis	Status	Test
S6	Stability before and after the impulse was defined: P1 on origins up to 2008Q3 vs from 2008Q4	Exploratory	Separate RMSE ratios with intervals
R1	Ragged-edge variants Y and Z (§6)	Robustness	Reported in full; never used to select the headline
E1	Replication of the López-Buenache et al. credit-contraction signal under real-time vintages, 2000–2019	Exploratory	Markov-switching model, filtered probabilities only (§8)
E2	The credit-revision premium comes from late-arriving source data (routine releases) rather than from redefinitions (benchmark releases). Run only if S1 shows a premium.	Exploratory	Trace each quarter's credit impulse through all 83 releases (1999–2019) and assign each revision step to the release that made it. A release is a benchmark release if its median absolute revision to the credit impulse, for quarters at least 12 quarters before its q*, exceeds 0.25 × the SD of the revised impulse; every other release is routine. The threshold is fixed before the revision paths are examined (agreed by Andy, 19 Oct 2026). Revisions from Dec 2019 to the current release cannot be split and are reported as one block. Descriptive revision shares only.
D1	Credit threshold signals preceded recessions	Descriptive	§10

The confirmatory core is P1a, P1b, P2a and P3, under Holm, and nothing else. Every other entry is exploratory or robustness, and the paper labels it that way in its own language, not as a second tier of tests. Exploratory results get no multiplicity correction and support no confirmatory claim. All are published, including nulls. P3 is in the core because it has one observation per quarter and no forecast overlap, making it likely the best-powered test.

Expectation statement (not a hypothesis). We expect the credit-revision premium for the impulse to be small, because data revisions were the secondary channel for credit gaps (Edge and Meisenzahl, 2011). If it is large, that is itself a finding. Given the benchmark-revision exposure noted in §1, this is a genuine gamble, not a safe prior. It adds **no test** to the confirmatory core: S1 remains exploratory and uncorrected for multiplicity, and the expectation is reported as confirmed or contradicted, nothing more.

D2 — Edge–Meisenzahl replication (descriptive, dataset validation). On this project's own Z.1 vintages, 1999–2019, decompose each quarter's credit-to-GDP gap revision (real-time minus latest) into two parts:

1. **Data-revision component:** the gap recomputed on latest-vintage data, but with the filter run only up to the origin quarter.
2. **End-point (filter) component:** everything else.

Report each part's share of revision variance. Reproducing their "mostly filter" result validates the vintage dataset and links this paper to theirs. A different result is reported as a finding.

D2 and S1 measure different objects. D2 is a variance decomposition of the *gap's revisions*, and it validates the dataset and confirms whether the filter was the gap's dominant problem. S1 is a difference of *forecast RMSE ratios*, and it asks a separate question: whether the residual data-revision channel, alone and unfiltered, changes the impulse's predictive content. Results from one are not read as evidence about the other.

4a. Interpretive map (pre-registered)

Results are interpreted only through this table. Any pattern not listed is reported as "unanticipated", with no post hoc explanation. Wording follows the power rule in §11. Exploratory results (E1) cannot move a reading between rows.

Headline map, written before lock. P1 is "positive" if it meets the support rule in §11. The credit-revision premium is **large** if it is at least 0.05 in RMSE-ratio units and its 90% bootstrap interval excludes zero, and **small** otherwise.

Headline outcome	Pre-committed sentence for the paper
Honest cell positive	"Credit carried predictive content that a forecaster could have used from data as published at the time."
Null, large premium	"The predictive content of credit reported in revised data depends on later revisions to the credit data; it was not available in real time."

Headline outcome	Pre-committed sentence for the paper
Null, small premium	"Credit shows no detectable predictive content in either real-time or revised data at this sample size; the published evidence does not rest on revisions, and given that the available credit variation is concentrated in 2008–09, the design could reliably detect only very large gains, of roughly 40% or more (RMSE ratio about 0.6; audit Entries 18–19)."

The detailed table below refines these readings; it never overrides them.

Pattern of results	Reading
P1 supported; credit-revision premium small	Predictive content was available in real time, and revised-data evidence holds up
P1 supported; premium large	Content exists in real time, but revised-data estimates overstate it
P1 null; revised-data cell positive; premium large	**Measurement story:** apparent content depends on revisions to the credit data
P1 null; premium small; S5 supported	**Specification story:** the signal is concentrated in contractions and averaged away by a linear model
P1 null; premium small; S5 null	**No evidence** of predictive content under real-time data at this sample size; only very large gains (roughly 40% or more) ruled out, because the credit variation is concentrated in 2008–09
P1b supported; P1a null	Content is specific to the labour market; consistent with, but not proof of, a financing-constraint channel
P3 supported	First-release GDP did not fully reflect information in published credit data; this stands whatever P1 shows
P2a supported	The information was in published data before the SPF deadline but not reflected in the median forecast

No row is a causal claim. The map interprets prediction patterns, not mechanisms.

5. Targets

- **Real GDP growth:** g_s = 100 × [(Y_s / Y_{s−1})^4 − 1], discretely compounded, where Y is real GDP, chained dollars, seasonally adjusted. This matches the annualisation used by BEA and the SPF, so model and SPF errors are on the same scale.
- **Unemployment:** u_s = mean of the three monthly civilian unemployment rates (SA) in quarter s. The target is the **level**. Because the base is known at the origin, RMSE on the level equals RMSE on the change from that base. Directional accuracy uses the sign of u_s − u_{o−1}, with u_{o−1} from the origin vintage; changes under 0.05 pp are dropped from the direction metric.
- **Horizon:** at origin o, the target is s = o + h, for h ∈ {1, 2, 4}; h = 4 is primary. This matches the SPF's four-quarter-ahead convention.
- **Revised target:** values from the RTDSM vintage dated 2026Q3 (ROUTPUT26Q3, RUC26Q3), downloaded 19 Oct 2026, frozen and hashed (SHA-256: ROUTPUTQvQd.xlsx 25433da0…, rucQvMd.xlsx d971e59d…; full hashes in audit Entry 13).
- **Early-estimate target:** the value for s in the RTDSM vintage dated quarter s + 2.
- **COVID exclusion by target quarter:** any forecast with s ⩾ 2020Q1 is excluded. The last included origin is 2018Q4 at h = 4, 2019Q2 at h = 2 and 2019Q3 at h = 1.

6. Information set, ragged edge and credit timing

- **Origin.** The origin date is the RTDSM vintage date for quarter o (middle month). GDP, unemployment, inflation and the 2-year yield are observed through o − 1 in that vintage, so non-credit variables have no ragged edge.
- **Credit availability.** At each origin, credit is taken from the latest Z.1 release dated before the origin date. Its last quarter is q*_o, and the gap k_o = o − q*_o is recorded as data, not chosen (typically 2). If a release is late, the latest earlier release is used and the larger k_o recorded.
- **Origin–release table.** In Phase 1, a table of (origin, Z.1 release date, q*_o, k_o) is built from release dates alone. It is dated and hashed before any forecast is computed.
- **Primary treatment: release-time lags.** Credit enters every model only at the lags actually published, X_{q**o}, X*{q*_o−1}, and so on. Nothing fills the gap between q*_o and o − 1, and no auxiliary model is used. This method was chosen on transparency grounds alone, before any forecast was computed; Phase 1 is descriptive only.
- **Robustness Y: AR imputation.** The 4-quarter credit flow S_t for quarters q*_o + 1 … o − 1 is forecast from an AR(4) on S_t alone, estimated on that Z.1 vintage up to q*_o. CI for those quarters is then computed, and models use calendar lags ending at o − 1.
- **Robustness Z: credit-only state-space model.** A VAR(2) on household and non-financial business flows, in state-space form, fills q*_o + 1 … o − 1 by Kalman forecast.

- **Gap-filler rule.** No gap-filler uses GDP, unemployment, inflation, interest rates or any other non-credit series to predict credit. Nominal GDP enters only as the published CI denominator, never as a predictor.
- **Reporting rule.** Primary is release-time lags, tested under Holm. AR imputation and the credit-only state-space model are reported in full as robustness, with RMSE ratios and intervals. Disagreement between them and the primary is reported, not adjudicated by selecting the favourable result.
- **Lock.** The rule text, the gap-filler code and the origin–release table are committed and SHA-256 hashed at lock.
- **Estimation history.** Estimation at each origin uses the full history as it appears in the origin's vintages (end-of-sample vintage convention).

7. Credit definitions

Stocks and flows are kept separate. Let L_t^(v) be the outstanding stock at the end of quarter t, and F_t^(v) the seasonally adjusted transactions flow during quarter t. Both cover households plus non-financial business, debt securities and loans, from Z.1 vintage v. Flows published at annual rates are divided by 4. Let N_t^(w) be the sum of quarterly nominal GDP (SAAR ÷ 4) over t − 3 … t, from GDP vintage w.

```
S_t^{(v)} = \sum_{j=0}^{3} F_{t-j}^{(v)} \qquad CI_t^{(v,w)} = 100 \times \frac{S_t^{(v)} - S_{t-4}^{(v)}}{N_t^{(w)}}
```

Measure	Built from	Definition	Role
Credit impulse	Flows	CI_t above; split into CI^+ = max(CI, 0) and CI^- = min(CI, 0) for S5	Primary
Credit growth	Stocks	100 × (L_t / L_{t−4} − 1)	S2
Credit-to-GDP gap	Stocks	R_t = 100 × L_t / N_t, minus a one-sided HP trend (λ = 400,000) estimated on R up to t within that vintage	S2
Real credit growth	Stocks	100 × [(L_t / L_{t−4}) ÷ (P_t / P_{t−4}) − 1], P = GDP deflator from the origin's RTDSM vintage; contraction indicator = 1 if negative	S2, S5, E1

Robustness: CI from stock differences, replacing S_t with L_t − L_{t−4}. The difference between the two is reclassifications and breaks, reported in the revision study.

Denominator vintage: real-time w = the RTDSM vintage at the origin, which always covers q*_o because GDP is published before Z.1. Revised w = the frozen latest vintage.

8. Models

All models are estimated on an expanding window from 1965Q1 (or the earliest quarter the vintage supports) and re-estimated at every origin. Robustness: a 60-quarter rolling window.

Model	Specification	Used in
Benchmarks	Random walk; 8-quarter mean; AR(1); AR(2)	Reference
Direct AR(2)	$y_{o+h} = \alpha + \varphi_1 y_{o-1} + \varphi_2 y_{o-2} + \varepsilon$	P1 benchmark
Direct ADL	Direct AR(2) + $\Sigma_{j=0}^{3} \beta_j X_{q^*-j}$, where X is the credit measure	P1, S1, S2
Asymmetric ADL	Direct AR(2) + $\Sigma \beta^{+}_j CI^{+}_{q^*-j} + \Sigma \beta^{-}_j CI^{-}_{q^*-j}$, j = 0…3; split fixed at zero, nothing estimated	S5
Contraction ADL	Direct AR(2) + real credit growth and its interaction with the contraction indicator, lags 0–3	S5
BVAR 1A	GDP growth, GDP deflator inflation, unemployment, 2-year yield; lag 2; data through o − 1	S4
BVAR 1B	1A + CI shifted by its release lag (CI_{t-2}), so credit enters only as published; when $k_o > 2$, the missing value is filled by the credit-only AR imputation (robustness Y). No conditioning on non-credit data	S4
SPF corrected	$SPF_{o+4|o} + \hat{\alpha}_o + \hat{\beta}_o \times CI_{q^*}$	P2
SPF bias-corrected	$SPF_{o+4|o} + \hat{\alpha}_o$	P2 benchmark
Markov-switching (E1)	Two-regime Markov-switching regression of Δu_t on a switching intercept and switching variance, with real credit growth at its release lag (RCG_{t-k}) as a non-switching regressor, estimated from 1965Q1 on data through o − 1 at each origin from 2000Q1. The filtered (never smoothed) probability of the rising-unemployment regime at o − 1 is added to the direct AR(2) for u_{o+4}, and scored by Clark–West against the AR(2) (specification agreed 19 Oct 2026, audit Entry 17)	E1

E1 targets: the unemployment level (as in P1b), and real-time slack only if CBO natural-rate vintages exist in ALFRED. Using today's natural rate would bring hindsight into the target.

Why direct. The ADL is direct, so it needs no forecast of credit, nests the direct AR(2) exactly, and keeps Clark–West valid.

BVAR prior (S4). Minnesota prior, identical hyperparameters in 1A and 1B: overall tightness 0.2, cross-variable 0.5, lag decay 2. Prior mean on the first own lag is 1 for unemployment and the 2-year yield, and 0 for GDP growth, inflation and CI. Scale parameters come from AR(4) residual variances on each estimation sample. Shrinkage makes Clark–West asymptotics non-standard, so S4 uses the HLN-corrected Diebold–Mariano test with a bootstrap and is read as supporting evidence only.

SPF alignment (P2), checked against the SPF documentation (July 2026):

- **Horizon.** In survey o, forecasters know GDP through o − 1 (the advance estimate) plus the employment report released in month 2 of o. Column suffix 6 is quarter o + 4, matching h = 4.
- **GDP target series.** The official median growth series (MedianGrowth.xlsx, dRGDP6) is the growth rate of the median *level* forecasts, not the median of individual growth rates. It is discretely compounded and annualised. **Primary:** dRGDP6 as published, because that is what a contemporary saw. **Robustness:** the median of each forecaster's own implied growth rate, from SPFmicrodata.xlsx. This avoids mixing different forecasters' levels across adjacent quarters.
- **Unemployment target series.** UNEMP6, the median forecast of the quarterly-average rate. It is a level, so no growth construction is needed.
- **Base years.** Level files use the base year in force at each survey and are never rescaled. Only growth rates enter P2a, so this does not matter.
- **Deadlines and sample.** Deadlines come from the Philadelphia Fed release-dates file. Only surveys from 1990Q3 onward are used: 1990Q2 was collected after the fact, and the timing of pre-1990 ASA/NBER surveys is not documented.
- **Credit.** CI_{q*} comes from the latest Z.1 release dated before the deadline d_o; typically q* = o − 2.
- **Correction.** $\hat{\alpha}$ and $\hat{\beta}$ are estimated by OLS on past surveys whose target quarter had been published by d_o. Errors are computed from values as published at d_o. At least 20 training pairs are required before the first evaluation, and evaluation is against the revised target. The bias-only benchmark stops a pure bias correction being credited to credit.
- **Information edge.** The SPF's extra month of labour-market data is left in place. It makes P2 harder to pass, not easier.

- **Implied sample.** A training pair from survey s becomes usable only once quarter s + 4 is published, so the first evaluation survey is about 1996Q3. That leaves at most about 90 evaluation surveys to 2018Q4, and fewer if Z.1 vintages start later.

9. P3 and S3 — revision tests

P3 (primary, GDP only).

- **Anchor date a_s:** the release date of the advance GDP estimate for quarter s (end of month 1 of s + 1).
- **Outcome:** R_s = g_s(revised) − g_s(advance).
- **Predictor:** CI from the latest Z.1 release before a_s (typically covering s − 1).
- **Controls (as published at a_s):** advance g_s and g_{s−1}.
- **Test:** OLS with HAC standard errors (4 lags); two-sided test of the CI coefficient, with p-value and 90% interval from a restricted wild (Rademacher) block bootstrap of the HAC t-statistic (block 4, 999 draws), because fixed-b HAC over-rejects (14–18%) when a few extreme CI values dominate (amended 19 Oct 2026, audit Entry 18). One observation per quarter.
- **Robustness:** revision measured to the last vintage before the next comprehensive revision, which removes definitional changes from R_s.

S3 (dropped, 17 Oct 2026: G3 failed, see audit Entry 7; text kept for the record).

- **Anchor:** the date GDI for s is first published.
- **Outcomes:** the GDP revision from that date, and the GDI revision.
- **Controls add:** GDI growth and the GDP–GDI growth gap at the anchor.

Reading. A non-zero coefficient means early estimates did not fully reflect information already in published Z.1 data ("noise" rather than "news" in the revision). It is not a claim that the statistical agency erred.

10. D1 — threshold signals

Rules (no free parameters), evaluated at each origin with data as then available:

1. CI negative for two consecutive available quarters.
2. 4-quarter credit growth below 4-quarter nominal GDP growth.

Episode definition.

- A signal belongs to its origin quarter.
- An **episode** is a run of consecutive signal quarters; runs separated by a single non-signal quarter are merged.
- **Hit:** the episode starts 1–6 quarters before an NBER peak (1990Q3, 2001Q1, 2007Q4).

- **Late:** the episode starts between the peak and the trough.
- **False alarm:** any other episode.
- **Miss:** a peak with no episode starting in the 6 quarters before it.
- Lead time = peak quarter − episode start.
- The share of all quarters spent in signal is also reported.

The revised version applies the same rules to revised data for the same data quarters. Published BIS thresholds are not used, because they were calibrated after 2008.

11. Power and power-dependent rules

Simulation, run in Phase 1 and published before lock:

- **DGP for P1 and P2:** the direct ADL, with CI following its own fitted AR process and measurement noise matching the Phase 1 credit revision variances.
- **DGP for P3:** the revision regression, with a CI effect calibrated to partial R^2 of 0.02, 0.05 and 0.10.
- **DGP for S5:** the asymmetric ADL, with an effect only in CI^-.
- **Design:** actual sample sizes (P1 origins from Phase 0; P2a at most about 90 surveys; P3 one observation per quarter), h = 4 overlap where relevant, HAC tests, and Holm across P1a, P1b, P2a and P3.
- **Effect sizes for forecast tests:** true RMSE ratios of 0.85, 0.90 and 0.95.
- **Replications:** 2,000.
- **Reported:** per-test and family-wise power, and the minimum detectable effect at 80% power. Result (specification-matched simulation, fixed-b, Holm, audit Entry 16): RMSE ratio 0.88 for P1a, 0.85 for P1b and 0.89 for P2a; partial R^2 just above 0.10 for P3. Holm-adjusted power at a true ratio of 0.90: P1a 0.71, P1b 0.58, P2a 0.75; P3 0.45 at partial R^2 0.05.

Pre-declared rules, selected by power at a true ratio of 0.90:

Power at 0.90	Primary tests	Support rule	Language for a null
⩾ 0.80	All four	Holm p < 0.05 and ratio ⩽ 0.95	"Not supported" if ratio ⩾ 1.00, else "inconclusive"
0.50–0.80	All four	Same	"Not detected; gains larger than [upper 90% bound] ruled out"

Power at 0.90	Primary tests	Support rule	Language for a null
< 0.50	P1a and P3 only; P1b and P2a move to exploratory	Estimation only: "credible improvement" if the 90% bootstrap interval for the RMSE ratio lies wholly below 1.00	No significance language; ratios and intervals reported

The rule is applied test by test (decision, 19 Oct 2026, before any forecast). Each confirmatory test's band is set by its own Holm-adjusted power at a true RMSE ratio of 0.90 (for P3, a partial R^2 of 0.05). **Inference uses fixed-b critical values** (Kiefer–Vogelsang, Bartlett kernel, b = (h − 1 + 1)/n), simulated once and frozen, because standard normal critical values with NW HAC over-rejected at these sample sizes (audit Entry 12).

Bands as applied (decision 19 Oct 2026, audit Entries 18–19; supersedes Entries 14 and 16): power is assessed conditional on the actual credit path, because the real credit impulse is dominated by one episode and a Gaussian simulation overstates power. On that basis all four confirmatory tests fall in the < 0.50 band. Each is therefore reported as an estimate with its 90% interval (block bootstrap for RMSE ratios; wild block bootstrap for P3), with "credible improvement" only if the whole interval lies below 1.00 (for P3, excludes zero). No significance language is used; Holm-adjusted p-values are reported for completeness only. Checked on synthetic data with the real credit path: the rule's false "credible improvement" rate is 0–2%, and it detects a true 7% gain 30–40% of the time.

The rule is chosen from simulation alone and written into the locked protocol.

Expectation statement. If the simulated minimum detectable RMSE ratio is below 0.95, meaning only gains larger than 5% can be detected, the protocol and the paper both state: *"Before seeing any results, we expected this design to detect only large improvements, because almost all the variation in the credit impulse comes from 2008–09; at the actual credit path, even a 10% gain would be detected less than half the time, and only gains of roughly 40% or more reliably. Smaller real effects may exist and go undetected."*

12. Inference details

- HAC standard errors with h − 1 lags.
- Giacomini–Rossi fluctuation test (20-origin window) to show *when* any gain occurs.
- Block bootstrap (block length 4) for premia and ratio intervals.
- Descriptive windows (calendar-fixed): 2000Q1–2002Q4 and 2007Q1–2010Q4 within the confirmatory sample; 1989Q3–1992Q2 in the exploratory hybrid-vintage extension only. The 2007–09 window is exploratory for all credit claims.

13. Graphs

- The grid as one chart of RMSE ratios with intervals (headline exhibit).
- Real-time vs revised CI, with recession shading added after the series are drawn.
- The k_o lag at each origin.
- Threshold timeline: real-time and revised rows, with episodes classified.
- Cumulative squared-error differences for P1 and P2, with the share of the total gain coming from origins 2007Q1–2010Q4 reported beside each, together with the signed total (added 19 Oct 2026, audit Entry 19).
- GDP and GDI revisions against real-time CI.

14. Out of scope and process

- Nowcasting is parked: quarterly Z.1 arrives after the first GDP estimate. DSGE comparisons and the euro area are also out of scope.
- Lock = tagged public commit (OSF or GitHub release) with this protocol, the mapping table, extraction logs, power results, code tested on synthetic data, and SHA-256 hashes of every raw file.
- A dated deviation log, each entry stating whether any results had been seen. All pre-registered outputs published, including nulls.

Phase 0 audit log

Entries are dated and are never edited after the fact; corrections are added as new entries.

Entry 1 — 17 Oct 2026: Z.1 vintage availability and series codes

Result: G1 passes from 1999Q3. Sample-start decision recorded in protocol §3.

Period of Z.1 releases	Source	Format	Quarterly history per vintage	Usable for
Jun 11, 1999 → present	Fed release archive, per-release "Historical data" page	Zip files from 1952Q1, incl. debt file for tables D.1–D.3 (example)	Full	Confirmatory sample

Period of Z.1 releases	Source	Format	Quarterly history per vintage	Usable for
Sep 12, 1996 → Mar 12, 1999	Fed release archive	Text PDF only (Mar 1999 page has no data link)	Last ~4.5 years	Exploratory extension
Mar 1988 → Jun 1996	FRASER	Scanned PDF with OCR text; OCR errors confirmed (e.g. "A" for "4") in the Mar 6, 1991 release	~5 years	Exploratory extension; double extraction required

Series codes, June 11, 1999 vintage (read from the release's coded tables; zip download was blocked from the workspace, so confirm against the zip when downloaded):

Concept	Flow, SA annual rate (D.2 / F.100, F.101)	Level, SA (D.3)	Current-vintage code
Households, credit market instruments	FA154102005	LA154102005	FL154104005 (households, debt securities and loans)
Nonfinancial business, credit market instruments	FA144104005	LA144104005	FL144104005 (unchanged)
of which nonfinancial corporate	FA104104005	LA104104005	—

Mapping finding: the household code changed between vintages (154102005 → 154104005), alongside the renaming of "credit market instruments" to "debt securities and loans". The business code is unchanged. Both must be linked in the mapping table, with the date of the change identified.

FRASER coverage, 1989–1996. All quarterly releases are present except two:

- **Dec 1991:** no December release; the Jan 31, 1992 "Annual Revisions" release appears to carry 1991Q3 data in its place.
- **Q3 1995:** no release between Sep 13, 1995 and Mar 8, 1996 (possibly the government shutdown).

Under the existing late-release rule (§6), affected origins use the latest earlier vintage and record a larger k_o. Year-end special editions ("Financial Assets and Liabilities", "Annual Total Flows") are not quarterly vintages and are excluded.

Open items from this entry:

- [ ] Download the June 1999 zip on a machine with access and confirm the codes above against the .prn headers
- [ ] Confirm what quarter the Jan 31, 1992 release covers, and search for a 1995Q3 release outside FRASER (Fed library or Board publications)
- [ ] Verify the series codes for at least one vintage per year 1999–2015, to date the household code change

Entry 2 — 17 Oct 2026: June 11, 1999 zip files downloaded and checked

Result: household codes confirmed in the raw files for flow, level and growth; business flow and growth confirmed. Business level, the D.2/D.3 files, the last-row check and the value spot check are still open.

File (table)	Codes found in header	Confirms
ltabs.zip (L.1, sector summary of levels)	FL154102005.Q; business as components FL104104005.Q, FL114102005.Q, FL134102005.Q	Household level code in this vintage is **FL154102005**; the current vintage uses FL154104005, so the code change is confirmed from the raw file
gtabs.zip (D.1, debt growth rates)	FG154102005.Q, FG144104005.Q	Household and business codes exist in the D-table set
atabs.zip (F.1, borrowing summary)	FA154102005.Q; business as components FA104104005.Q, FA114102005.Q, FA134102005.Q	Household flow code. FA894104005.Q appears twice: the second half of a two-part file
atabs.zip, atab100d.prn / atab101d.prn (F.100, F.101)	FA154102005.Q / FA144104005.Q	Household and business flow codes (as reported by Andy)

File hashes (SHA-256):

File	SHA-256
gtabs.zip	F55C45BEC616807F2BF1E3FF83005606C668562E24FBD990B0B325794350A55E

File	SHA-256
atabs.zip	D0269B923838D45873CDC901486675AF56AB4D4AC15D3EC1597C031385A80F89
ltabs.zip	423F13B585CC04FADE3D0BB0A8F78D905B610F0AF96CB386E29A107E35E5E779

Open items from this entry:

- [ ] ltab101d.prn: confirm FL144104005.Q (business total, level)
- [ ] gtabs.zip D.2 and D.3 files: confirm FA154102005.Q, FA144104005.Q, LA154102005.Q, LA144104005.Q
- [ ] Confirm the last row of each file is 1999Q1
- [ ] Spot-check household borrowing, 1999Q1, in the gtabs D.2 file against table D.2 of the June 1999 PDF

The first open item of Entry 1 (confirm codes against the zip) is partly closed by this entry.

Entry 3 — 17 Oct 2026: Entry 2 checks 1–3 closed

Result: all four series codes are confirmed in the raw June 1999 files, and every file ends at 1999Q1. Only the value spot check remains.

- ltab101d.prn contains **FL144104005.Q** (business total, level).
- gtab2d.prn (D.2, borrowing) contains **FA154102005.Q** and **FA144104005.Q**.
- gtab3d.prn (D.3, debt outstanding) contains **LA154102005.Q** and **LA144104005.Q**.
- gtab1d.prn (D.1) has none of these codes, as expected: it holds growth rates under FG codes.
- Last row is 1999Q1 in all files checked.

Spot-check values from the printed release (table D.2 and D.3, June 1999 PDF, 1999Q1, $ billions):

Series	Printed value	Value in file
FA154102005.Q households, borrowing (SAAR)	556.3	556.25 (match)
FA144104005.Q business, borrowing (SAAR)	498.1	498.14 (match)
LA154102005.Q households, outstanding (SA)	6041.4	6041.37 (match)
LA144104005.Q business, outstanding (SA)	5337.5	5337.51 (match)

- [ ] Fill the file values and confirm they round to the printed values

Format note (from gtab2d.prn): dates are written "199901" (year + two-digit quarter); D.2 values are $ billions at seasonally adjusted annual rates, two decimals.

Spot check passed (17 Oct 2026): all four file values round to the printed release values. The June 11, 1999 vintage is confirmed for codes, units, last quarter and values. G1 data-source check for this vintage: **pass**.

Entry 4 — 17 Oct 2026: code-change date, release dates, SPF deadlines, GDI coverage

Result: the household code change is dated to Sep 2010. Both date tables are built. G4 passes. G3 is provisionally failing, so S3 is likely dropped while P3 runs on GDP alone.

1. Household code change. Checked in the Fed's coded tables (table D.2/D.3) release by release:

Release	Household code	Business code
Jun 11, 1999 → Jun 10, 2010 (checked: 1999, 2003, 2007, Mar 2009, Dec 2009, Mar 2010, Jun 2010)	154102005	144104005
Sep 17, 2010 → present (checked: Sep 2010, Dec 2010)	154104005	144104005

The Sep 2010 coded tables also reorder the D-table columns (federal government moves position). **Rule added to the mapping table: parse columns by series code, never by position.** The Sep 2010 release separately announced further identifier changes from Dec 9, 2010, and those are covered by the same rule. Still to do: confirm the switch in the Sep 2010 gtabs.zip headers (data page).

2. Z.1 release-date table. 95 releases, Sep 1996 → Mar 2020, transcribed from the Fed release-dates page, with format and household code per release (file: z1_release_dates.csv). Points to note:

- The 2003Q3 data came out on **Jan 15, 2004**; there was no December 2003 release.
- Dates are taken from the archive folder names. One looks wrong ("20170305" is a Sunday), so G2 requires checking each date against the release's own cover page before lock.

3. SPF deadlines. All 118 surveys from 1990Q3 to 2019Q4, from the Philadelphia Fed release-dates file, are linked to the latest Z.1 release before each deadline (file: spf_deadlines_z1_map.csv).

- From 1999Q3 to 2019Q4, **k = 2 in 81 of 82 surveys**. The exception is 2019Q1, whose deadline the shutdown pushed to Mar 12, 2019, after the Mar 7 Z.1 release, so k = 1. The protocol's "typically 2" is confirmed.
- Shutdown-delayed surveys: 1996Q1, 2013Q4 and 2019Q1.
- **G4: pass.** All deadlines are documented; the evaluation sample is well above 40 surveys.

4. GDI vintages in ALFRED (provisional). ALFRED's record for GDI appears to begin on **Dec 20, 2012**. That would give about 29 target quarters before 2020, against the 60 that G3 requires, so **G3 provisionally fails**. Before deciding, check whether:

- [ ] ALFRED's "all vintages" download confirms the Dec 2012 start
- [ ] BEA's archive of past NIPA releases supplies first-release GDI for 1999–2012, which would mean PDF extraction

If neither source closes the gap, S3 is dropped as the protocol specifies, and P3 runs on GDP alone.

Entry 5 — 17 Oct 2026: GDI vintage start confirmed

Result: ALFRED's earliest GDI vintage is 2012-12-20, read from the vintage selector on the ALFRED GDI page (Edit Graph → select a vintage). First-release GDI is therefore available for target quarters from about 2012Q3 only, roughly 30 quarters before 2020, against the 60 that G3 requires.

- A first download (alfredgraph.xlsx, created 2026-10-17) contained only the two most recent vintages (2026-08-26, 2026-09-30), the ALFRED default, so it was not used for this check.
- G3 stays **provisionally failing**. Two routes remain before a final decision:
  - [ ] Check the earliest vintage of A261RC1Q027SBEA, nominal GDI under BEA's own code
  - [ ] Decide whether to extract first-release GDI for 1999–2012 (about 54 quarters) from BEA's Survey of Current Business PDF archive
- If both routes fail, or the extraction is judged not worth the cost for an exploratory test: **G3 fails, S3 is dropped as pre-registered, and P3 runs on GDP alone.** This does not affect the confirmatory core.

Entry 6 — 17 Oct 2026: second GDI series checked

Result: real GDI (A261RX1Q020SBEA) has its earliest ALFRED vintage on 2013-02-28, later than nominal GDI (2012-12-20). The series ID A261RC1Q027SBEA suggested in Entry 5 does not exist (404) and is withdrawn. No ALFRED GDI series covers 1999–2012.

Decision pending (Andy): extract about 54 quarters of first-release GDI from BEA's Survey of Current Business PDFs, or record **G3: fail → S3 dropped; P3 runs on GDP alone**. Recommended: record the fail. S3 is exploratory, and the extraction cost is high relative to its value.

Entry 7 — 17 Oct 2026: G3 decision

Decision (Andy): G3 is recorded as failed. No ALFRED GDI series has vintages before Dec 2012 (Entries 5–6), and extracting first-release GDI from BEA PDFs was judged not worth the cost for an exploratory test.

Consequences, applied to the protocol before lock:

- **S3 is dropped.** Its row in §4 and its text in §9 are marked as dropped, not deleted.
- **P3 is unchanged.** It is anchored to the advance GDP estimate and never depended on GDI.
- **The confirmatory core is unchanged:** P1a, P1b, P2a and P3, under Holm.

Gate status after Phase 0 so far: G1 pass (from 1999Q3) · G2 pending (release dates to verify against cover pages) · G3 fail · G4 pass.

Entry 8 — 17 Oct 2026: G2 spot check of Z.1 release dates

Result: 8 of 83 in-scope release dates checked against the releases' own pages. Seven match; one is corrected. G2 stays pending until all 83 are verified.

Folder date	Printed date	Source	Status
1999-06-11	June 11, 1999	data page	Match
2001-09-18	Tuesday September 18, 2001	cover PDF	Match (delayed after 9/11)
2003-06-05	June 5, 2003	release page	Match
2004-01-15	January 15, 2004	cover PDF	Match (2003Q3 data; no Dec 2003 release)
2008-12-11	December 11, 2008	release page	Match
2013-09-25	September 25, 2013	release page	Match

Folder date	Printed date	Source	Status
2017-03-05	**March 9, 2017**	cover PDF	**Corrected**: the archive folder name is not the release date
2019-09-20	September 20, 2019	release page (last update)	Match

- Only one in-scope folder date fell on a weekend (2017-03-05), and that was the error.
- The correction does not change the SPF mapping: the 2017Q2 deadline (May 9) falls after either date.
- **Lesson for the mapping table:** archive folder names are identifiers, not dates. Every date must come from the release itself.

- [ ] Verify the remaining 75 dates by running verify_z1_dates.ps1 (reads each release page and flags mismatches); record the result as a new entry

Entry 9 — 17 Oct 2026: G2 complete

Result: all 83 in-scope Z.1 release dates (Jun 1999 → Dec 2019) are verified against the releases' own pages. G2: pass.

- verify_z1_dates.ps1, run by Andy on 17 Oct 2026, read every release page and flagged one mismatch: folder 20160609, whose page shows "Last update" 2016-09-09.
- That release's cover PDF prints **June 9, 2016** (First Quarter 2016), so the table date is correct. The page's "last update" reflects a later re-posting, not the release.
- Including the 2017 correction in Entry 8, the release-date table has **one corrected date and no other errors**.

Phase 0 gate summary: G1 pass (confirmatory sample from 1999Q3) · G2 pass · G3 fail (S3 dropped) · G4 pass. **Phase 0 go decision: GO.**

Entry 10 — 19 Oct 2026: Phase 1, credit vintages downloaded and parsed

Result: all 83 releases (Jun 11, 1999 → Dec 12, 2019) plus the current release downloaded with none missing. Household and business borrowing (flow, SAAR) and debt outstanding (level, SA) extracted from every vintage and expressed in $ billions. Parser: 84 vintages OK, 0 flags.

File formats:

Releases	File	Debt tables	Units
Jun 1999 → Dec 2010	Disk/gtabs.zip (.prn)	gtab2d.prn (D.2), gtab3d.prn (D.3)	**$ billions**
Mar 2011 → Jun 2016	Disk/gtabs.zip (.prn)	gtab2d.prn, gtab3d.prn	**$ millions**
Sep 2016 → Dec 2019	z1_csv_files.zip	d2.csv, d3.csv	$ millions
Current (Sep 2026)	z1_csv_files.zip	**D3_t.csv** (transactions), **D3_s.csv** (levels); D.2/D.3 merged and renamed "D3"	$ millions

Findings:

1. **Undocumented units switch at the Mar 10, 2011 release.** The .prn debt files moved from billions to millions with no change in file names. It was detected by the parser's continuity check as a median level ratio of **exactly 1000.000** between the Dec 2010 and Mar 2011 vintages, then a ratio of 0.001 at the Sep 2016 format change under an earlier rule. **Rule adopted:** divide by 1,000 for every vintage from Mar 10, 2011 onward. After the fix, no consecutive pair of vintages differs by more than a factor of 2 in median level.
2. **Table renaming in the current release:** D.2 and D.3 are now D3_t and D3_s. Added to the mapping table.
3. **Plausible large revisions to spot-check later:** 2019Q3 levels in the Dec 2019 vintage vs today: households $15,985bn → $15,759bn; business $15,987bn → $17,047bn (+$1,060bn).

Process notes: the continuity check was first run quarter by quarter on flows as well as levels, which gave thousands of false flags (flows cross zero). It was replaced by a median ratio on levels only, before any results were examined. Files: download_z1.ps1, parse_z1.py (v4), download_log.csv (SHA-256 per file), credit_vintages_long.csv, parse_report.csv.

Entry 11 — 19 Oct 2026: Phase 1, real-time credit dataset, revision study and D2

Result: credit flows are revised modestly; the credit-to-GDP gap is revised heavily, and almost entirely because of the filter's end point, not the data. This is descriptive only. No forecasts were computed.

Build decisions (fixed before any results were examined):

- Common start 1953Q1. Quarterly flow = SAAR/4. Credit = households + nonfinancial business.

- RTDSM vintages dated to the 15th of the middle month. Each Z.1 vintage is paired with the latest RTDSM vintage published before its release date, which supplies the GDP denominator and the deflator.
- Origin–release table: 82 origins (1999Q3–2019Q4). The latest Z.1 release before each origin gives q* and k. **k = 2 at every origin.**
- Three versions per quarter: *real time* (first release); *credit-revised* (current Z.1 credit, real-time GDP, which isolates credit-data revisions for S1); and *revised* (current Z.1 with the latest GDP vintage).
- Gap: one-sided HP filter, λ = 400,000, at least 40 quarters of history, recomputed in every vintage. The final gap for D2 is a two-sided HP filter on revised data through 2019Q4. Ending the filter in 2026 instead moves the 1999–2019 final gap by up to 3.3 pp, so it is reported as a sensitivity check.

Validation: every Z.1 release has a GDP vintage covering q*. corr(ΔL, F) = 0.98 in the Dec 2019 vintage. Hand check: CI for 2008Q3 in the Dec 2008 vintage = (1,036 − 2,101) / ≈14,200 = −7.49, which matches the pipeline.

Revision statistics, first release vs revised, 83 quarters (1999Q1–2019Q3):

Measure	Mean revision	SD revision	Noise/signal	Corr	Sign agreement
Credit impulse (CI)	+0.03	0.95	0.28	0.96	86%
Credit growth (CG)	−0.19	0.69	0.18	0.99	98%
Real credit growth (RCG)	−0.30	0.70	0.21	0.98	95%
Gap, data part only	−1.13	1.32	0.14	0.99	100%

Findings:

1. **GDP revisions barely matter for CI.** Credit-only revisions (noise/signal 0.28) are as large as total revisions (0.28), so the S1 credit-revision premium is the relevant object. CG involves no GDP, so its credit-only and total revisions are identical by construction.
2. **CI is noisier in expansions than in recessions** (noise/signal 0.38 vs 0.21). The largest revisions came at the 2008 turning point: 2008Q3 first release −7.5 vs revised −5.2.
3. **D2: the filter accounts for essentially all of the gap's unreliability.** Variance shares of the total gap revision: data 3%, end-point filter 108%, covariance −11%. Mean absolute revision: data 1.4 pp vs filter 7.0 pp. Corr(real-time, final) = 0.65; the sign agrees in 76% of quarters. This replicates Edge–Meisenzahl in a new sample. It also supports keeping the gap exploratory and putting the flow measures at the centre.

Caption note, Fig. 2 (gap): the real-time gap moves for reasons that have nothing to do with credit.

- **It rose during the 2001 recession** (4.5 → 11 by 2003Q2). Credit kept growing at 7–9% while GDP slowed, so debt/GDP jumped from 137% to 152%. This is a denominator effect, a known flaw of the credit gap (Repullo and Saurina, 2011).
- **It fell in 2003–05** (11 → 8) while credit was accelerating (7.5% → 9.3%). Debt/GDP had flattened and the one-sided trend was still catching up with the earlier jump. It was not a warning signal.
- **It stayed near 10 through 2005–08.** Debt/GDP rose 21 points, but the trend absorbed 18 of them. In 2009Q2 the gap still read +5.8.

The final two-sided gap, rising steadily to +19 in 2008, relies on hindsight about the 2010s deleveraging. The real-time warning before 2008 appears in the impulse, which fell from about +4 in early 2006 to about −1 by mid-2007 (Fig. 1), not in the gap. Whether that warning had forecasting value is left to P1/P2a.

Files: build.py, build2.py, study.py, charts.py; origin_release_table.csv, credit_measures_by_vintage.csv, credit_measures_revised.csv, first_release_vs_revised.csv, revision_stats.csv, gap_decomposition_D2.csv; fig1_first_release_vs_revised.png, fig2_gap_decomposition_D2.png.

Still to do in Phase 1: power simulation (§11); placeholders; lock.

Entry 12 — 19 Oct 2026: Phase 1, power simulation (§11)

Result: at a true RMSE ratio of 0.90, Holm-adjusted power is 0.82 for P1a, 0.75 for P1b, 0.82 for P2a, and 0.53 for P3 (partial R^2 0.05). The minimum detectable effect at 80% power is a ratio of about 0.90 (a 10% gain). Gains of 5% are detected about half the time. No forecasts on actual data were computed.

Design (written before the run):

- **Data-generating process.** AR(2) processes fitted to revised CI, GDP growth and the unemployment level, 1955Q1–2019Q4. The shocks are jointly normal, using the residual covariance from those fits. Credit's effect is *imposed*: κ × CI at lag 6 ($q^* = o - 2 \rightarrow$ target $o + 4$), with κ chosen by bisection on a 300,000-quarter population run so that the true RMSE ratio of the direct ADL against AR(2) equals the stated value. The credit–target relationship was never estimated on real data.
- **Real-time noise.** The value at the edge ($o - 2$) carries $N(0, 0.946^2)$, the total revision SD of CI from Entry 11. Training rows use settled values.
- **Tests.**
  - P1a and P1b: 78 origins (1999Q3–2018Q4); expanding OLS from 1955Q3; the training sample ends at target $\leq o - 1$; Clark–West with NW HAC ($h - 1 = 3$ lags), one-sided.
  - P2a: an SPF proxy = the population AR-information forecast plus $N(0, 0.5^2)$ idiosyncratic noise; bias-corrected benchmark; correction trained from 1969Q1.

- P3: 82 quarters, partial R^2 of 0.02, 0.05 and 0.10, two-sided NW t-test (3 lags).
- Holm across all four tests. 2,000 replications per cell.

True ratio (P3 R^2)	P1a	P1b	P2a	P3	Any rejection	All four
1.00 (0) — size	0.024	0.034	0.023	0.032	0.083	0.000
0.95 (0.02)	0.51	0.41	0.52	0.20	0.66	0.10
0.925 (0.02)	0.69	0.58	0.69	0.25	0.81	0.17
0.90 (0.05)	**0.82**	**0.75**	**0.82**	**0.53**	0.91	0.43
0.875 (0.05)	0.90	0.87	0.90	0.56	0.96	0.50
0.85 (0.10)	0.94	0.93	0.94	0.85	0.98	0.80

Holm-adjusted power; unadjusted power is in power_results_R2000.csv.

Findings needing a decision before lock:

1. **Size distortion.** Under the null, unadjusted rejection rates are 5.9% (P1a), 7.8% (P1b), 5.8% (P2a) and 8.8% (P3), against a nominal 5%. The family-wise false-positive rate is 8.3% against a nominal 5%. NW HAC with a small n over-rejects. *Proposed:* use fixed-b critical values (Kiefer–Vogelsang), as listed in the red-team fix (§6c), and re-run the size row only.
2. **Which wording rule applies.** Read test by test at a ratio of 0.90: P1a and P2a fall in the ≥ 0.80 band; P1b and P3 fall in the 0.50–0.80 band. No test falls below 0.50, so none moves to exploratory. *Proposed:* apply the rule test by test, which needs one clarifying sentence in §11.
3. **The expectation statement in §11 is worded backwards.** "Minimum detectable ratio above 0.95, meaning only gains larger than 5% can be detected" should read "below 0.95". Read as intended, the statement is triggered: the minimum detectable ratio is about 0.90.

Caveats: credit acts through a single lag; edge noise is i.i.d.; the SPF is a stylised proxy; P3 errors are i.i.d. Each caveat is a simplification and is reported as such.

Files: calib.py, power.py, calib.npz, power_results_R2000.csv.

Entry 13 — 19 Oct 2026: power re-run with fixed-b inference; placeholders filled

Decisions applied (Andy, 19 Oct 2026, before any forecast): fixed-b critical values; the §11 rule applied test by test; the §11 expectation-statement wording corrected ("above" → "below" 0.95).

Fixed-b critical values for the Bartlett-kernel NW t-statistic with 3 lags (b ≈ 0.05), simulated with 20,000 draws at T = 2,000: one-sided 5% = 1.781 (n = 78); two-sided 5% = 2.091 (n = 82). These agree with the Kiefer–Vogelsang (2005) polynomial approximation (1.757 and 2.105) to within simulation error. The full simulated null distributions are used for p-values, which then enter Holm.

True ratio (P3 R^2)	P1a	P1b	P2a	P3	Any rejection	All four
1.00 (0) — size, unadjusted	0.050	0.066	0.044	0.074	—	—
1.00 (0) — size, Holm	0.020	0.026	0.017	0.021	0.064	0.000
0.95 (0.02)	0.45	0.36	0.46	0.17	0.61	0.08
0.925 (0.02)	0.64	0.53	0.64	0.21	0.76	0.14
0.90 (0.05)	**0.77**	**0.70**	**0.77**	**0.48**	0.89	0.37
0.875 (0.05)	0.87	0.82	0.87	0.51	0.94	0.44
0.85 (0.10)	0.91	0.90	0.91	0.82	0.98	0.75

Findings:

1. **Size is mostly fixed.** The family-wise false-positive rate falls from 8.3% to 6.4%. A residual excess remains for P1b (6.6%) and P3 (7.4%), against a Monte Carlo SE of about 0.5 pp; it is reported, not corrected further.
2. **Minimum detectable effect at 80% (Holm):** RMSE ratio 0.89 for P1a and P2a, 0.88 for P1b; partial R^2 of about 0.095 for P3. The expectation statement is triggered.
3. **Bands, test by test:** P1a, P1b and P2a fall in the 0.50–0.80 band ("not detected; gains larger than [upper 90% bound] ruled out"). **P3 = 0.48, just below 0.50:** decision pending (see below).

Revised-target vintage frozen: RTDSM 2026Q3, downloaded 19 Oct 2026. SHA-256:

- ROUTPUTQvQd.xlsx 25433da00f46764a167590efe5c3e1c20a3e91e98ba0f49e6f92f058bc42c9e3

- PQvQd.xlsx c9f7336fab2e8559c2730a69c86fb36a5324d2651a81d767491220f637dbedd1
- routput_fst.xlsx 2bffa7a68ad43a950a04cb378a368b5e59192b1febcfe22d2a0e110132bfc9c5

Placeholders filled: the revised-target date (§5), the minimum detectable ratio (interpretation map, two cells), the §11 result, and the expectation-statement value. Placeholders that remain by design: "[upper 90% bound]", which is filled from results; the E2 benchmark threshold, awaiting sign-off.

Files: fixedb.py, power.py (fixed-b version), power_results_fixedb_R2000.csv. The earlier normal-critical-value run (Entry 12) is kept for the record.

Entry 14 — 19 Oct 2026: decisions on P3 and E2

- **P3 (decided by Andy):** the §11 rule is applied as written. Power of 0.48 at partial R^2 0.05 is below 0.50, so P3 is reported as an estimate only, with no significance language. The effect-size pairing was not revisited after the power results were seen. P3 stays in the confirmatory core and the Holm family.
- **E2 (decided by Andy):** the benchmark-release threshold of 0.25 × SD of the revised impulse is agreed.
- **Still required before lock (§14):** Phase 2 analysis code written and tested on synthetic data only; the SPF input files (MedianGrowth.xlsx, SPFmicrodata.xlsx and the median unemployment file) downloaded and hashed; the lock bundle assembled and published as a tagged public commit.

Entry 15 — 19 Oct 2026: SPF input files downloaded, hashed and checked

Result: all four files were downloaded from the Philadelphia Fed (all versions dated 14 Aug 2026), and the hashes computed on Andy's machine match those recomputed after upload. The layouts are as the protocol assumes.

File	Bytes	SHA-256
medianGrowth.xlsx	144,611	FDCF9CA0299DE022C58F8FC35FD20761D8E52B45E038781AE3C4826D1A3CBB5C
medianLevel.xlsx	554,444	D296E737331C406F7680414504A0D005472743709387F8FDA6D969A1D2200977
SPFmicrodata.xlsx	24,612,638	D45AF2EAEBE11E8C7A0635D3F868D5D85897E5BC5CC3D8CB477C243B31FAA076
spf-caveats.pdf	15,843	D29674D2E6816C14A86755C7BA8D0922993A1ECBBEE7CA4321E1993B863F126F

Layout checks:

1. **GDP.** The growth file's RGDP sheet holds columns drgdp2–drgdp6 (lower case in the file; "dRGDP6" in the protocol refers to drgdp6). Hand check, 2008Q1 survey: (RGDP6 / RGDP5)^4 − 1 = (11,989.93 / 11,898.11)^4 − 1 = 3.12%, which matches drgdp6 = 3.1227. This confirms that drgdp6 is the discretely compounded, annualised growth of the median levels, for quarter o + 4.
2. **Unemployment.** UNEMP6 is in the level file's UNEMP sheet, for quarter o + 4.
3. **Coverage.** Both series start with the 1968Q4 survey; 5 surveys between 1969 and 1974 are missing. Correction training therefore has far more than the 20 pairs required before 1999Q3.
4. **Microdata.** The RGDP sheet has one row per forecaster per survey (YEAR, QUARTER, ID, INDUSTRY, RGDP1–RGDP6). In 1999–2019 there are 29–53 forecasters per survey (median 40.5).
5. **ID caveats** (spf-caveats.pdf). IDs may be reused in the NBER/ASA era, and may follow either the firm or the person after a job change. **Not material here:** the robustness series needs IDs only *within* a single survey, to pair one forecaster's RGDP5 and RGDP6. It never tracks IDs across surveys.
6. **Note.** Before 1992 the SPF's output variable is real GNP. This is consistent with the RTDSM, whose early vintages also measure GNP, provided targets are always taken from the vintage rule in §5. It affects correction training only, not the evaluation sample.

No forecast was computed, and no SPF error was examined.

Entry 16 — 19 Oct 2026: power simulation corrected to match the protocol's model specification

Error found (by Claude, while reading §6–§10 to write the Phase 2 code; no forecasts had been computed). The simulations in Entries 12–13 departed from the locked-text specification in four ways:

1. The ADL used one credit lag, where §8 specifies X_{q*−j} for j = 0–3.
2. Estimation started in 1955, where §8 specifies 1965Q1.
3. The SPF correction trained from 1969 with a free coefficient on the SPF, where §8 specifies SPF + $\hat{\alpha}$ + $\hat{\beta}$·CI_{q*}, with the SPF coefficient fixed at 1, trained on surveys from 1990Q3 only.
4. P3 omitted the §9 controls (advance g_s and g_{s−1}) and used 3 HAC lags instead of 4, with n = 82 instead of 83 (s = 1999Q2–2019Q4).

Entries 12–13 are superseded for the rule selection but kept for the record.

Corrected run (power2.py; fixed-b nulls for n = 78 with 3 lags and n = 83 with 4 lags; 2,000 replications). P2a's power is read against its own true ratio: under the restricted correction, a given credit effect yields a smaller SPF gain.

True ratio (P3 R^2)	P1a	P1b	P2a (own ratio)	P3	Any rejection	All four
1.00 (0), size, unadjusted	0.047	0.067	0.040	0.070	—	—
1.00 (0), size, Holm	0.012	0.024	0.014	0.021	0.063	0.000
0.95 (0.02)	0.35	0.28	0.28 (0.96)	0.18	0.54	0.06
0.925 (0.02)	0.55	0.39	0.46 (0.94)	0.17	0.68	0.08
0.90 (0.05)	**0.71**	**0.58**	0.63 (0.92)	**0.45**	0.85	0.27
0.875 (0.05)	0.81	0.69	0.74 (0.90)	0.48	0.91	0.35
0.85 (0.10)	0.88	0.79	0.83 (0.88)	0.79	0.96	0.62

Holm-adjusted power at a true ratio of 0.90: P1a 0.71, P1b 0.58, P2a 0.75 (interpolated at its own ratio of 0.90), P3 0.45. **Minimum detectable effect at 80%:** ratio 0.88 for P1a, 0.85 for P1b and 0.89 for P2a; partial R^2 just above 0.10 for P3.

Consequences. The band assignments are unchanged: P1a, P1b and P2a are in 0.50–0.80, and P3 is below 0.50, so it is reported as an estimate only (Entry 14 decision stands). The minimum-detectable-effect values in §4a, §11 and the expectation statement are corrected from "about 11%" to about 12% (GDP) and 15% (unemployment). The size excess remains: 6.3% family-wise; P1b 6.7%; P3 7.0%.

Lesson for Phase 2: the analysis code is written directly from §6–§10, and each specification element is listed against the protocol section that defines it.

Entry 17 — 19 Oct 2026: Phase 2 code written and tested on synthetic data; protocol fixes

Code. phase2.py implements §5–§10 in full: information sets, models, the core tests with Holm, the grid and S1, S2, S4 (Minnesota BVAR), S5, S6, R1 (Y and Z), E1, E2, D1, the rolling-window and h = 1, 2 robustness checks, and the unemployment direction metric. Real mode refuses to run without LOCK.json (release URL, tag commit, DOI).

Synthetic tests (test_phase2.py). Credit is real; all targets, GDP and unemployment vintages, SPF series and yields are simulated, so no real outcome was read.

- Sample sizes match the protocol: P1a, P1b and P2a 78 each; P3 83; 32 SPF training pairs at the first origin.
- A planted P3 effect of 0.80 is recovered as 0.77–0.80.
- Over 30 seeds, the false-positive rate for the forecast tests is 3%. The full run takes 24 s.

- Two coding bugs were found and fixed: E1 parameter indexing, and a date/lag misalignment in E1.

Disclosure: D1 seen before lock. D1 uses only credit data and NBER dates, so the synthetic smoke test computed the real D1 result. In 2001 and 2007–08, both real-time signals switched on at or after the peak ("late"). D1 is descriptive, uses no forecast target and has no decision attached. It is recorded here as seen before lock.

Protocol fixes (agreed by Andy):

1. The §2 premium sign is corrected (real-time ratio minus revised-credit ratio; positive means revised credit forecasts better).
2. The E1 specification is written into §8.

New input. FRED GS2 (2-year Treasury, monthly, 1976-06 to 2026-09), 9,742 bytes, SHA-256 57607a5c6474c1ea02f7f3aac5600f63a3157ef357c2afc05e63f9c69f56bab5. Quarterly averages over complete quarters; the BVAR sample starts in 1976Q3.

Entry 18 — 19 Oct 2026: power conditional on the actual credit path; P3 size

Finding. In synthetic runs using the real credit path, almost all of credit's forecasting gain comes from the 2008–09 collapse. The Clark–West loss differential is then highly skewed, and the test has little power even for large average gains. The earlier simulations (Entries 12, 13 and 16) drew CI from a Gaussian AR(2) and did not capture this. A simulation conditional on the actual revised credit path (power_realpath.py; targets, vintages and SPF simulated; 200 replications per cell) gives:

Median true ratio (P1a / P1b / P2a)	Unadjusted power P1a	P1b	P2a	Holm P1a	Holm P1b	Holm P2a
~1.02–1.04 (null)	0.055	0.045	0.035	0.015	0.005	0.010
0.96 / 0.97 / 0.97	0.33	0.26	0.34	0.07	0.12	0.07
0.91 / 0.93 / 0.93	**0.45**	**0.31**	**0.51**	0.09	0.12	0.11
0.82 / 0.85 / 0.86	0.57	0.43	0.71	0.10	0.13	0.11

The Holm figures are further depressed in this harness because a P3 effect was planted alongside, so P3 is rejected first and the remaining tests face thresholds of 0.05/3 and below.

P3 size. Conditional on the real credit path, the fixed-b HAC test of P3 over-rejects: 14–18% at a nominal 5%, because a few extreme CI values dominate. A restricted wild (Rademacher) block bootstrap-t (block 4, 999 draws) gives 3.5% size, and power of 0.43 at a modest planted effect.

Decisions pending before lock (Andy):

- (a) whether the §11 bands are set from the conditional-on-path power. Under that power every confirmatory test falls in the < 0.50 band (estimate only).
- (b) whether P3 inference moves to the wild block bootstrap.

No real target or SPF error has been examined.

Entry 19 — 19 Oct 2026: decisions on conditional-path power, P3 inference and the crisis share

Decisions (Andy, 19 Oct 2026; no real target or SPF error examined):

1. The §11 bands are set from power conditional on the actual credit path. All four confirmatory tests fall in the < 0.50 band and are reported as estimates with 90% intervals; "credible improvement" applies only if the interval lies wholly below 1.00 (for P3, excludes zero). This supersedes the band assignments of Entries 14 and 16.
2. P3 uses a restricted wild (Rademacher) block bootstrap of the HAC t-statistic (block 4, 999 draws) for its p-value and 90% interval (§9 amended). The fixed-b HAC p-value is retained in the output for comparison only.
3. A descriptive statistic is added to §13: the share of the total squared-error gain from origins 2007Q1–2010Q4, reported with the signed total.

Checks of the new rule (ci_check.py; real credit path, simulated targets; 100 seeds; 500 bootstrap draws). False "credible improvement" rate with no true effect: P1a 0%, P1b 2%, P2a 2%. With true ratios of 0.92–0.94: detected 32%, 29% and 40% of the time.

Reliable detection threshold. From the conditional-path runs (Entry 18 and test_phase2.py), unadjusted P1a power is 0.57 at a ratio of 0.82 and 0.87 at 0.52. 80% power therefore needs a ratio of about 0.6, a gain of roughly 40%. The §4a null sentence, the interpretive-map cell and the expectation statement now say this, replacing the earlier 11–15% figures.

Code updated: phase2.py (wild_block_t, crisis_share, estimate-only bands and the credible-improvement flags). Synthetic smoke test passes (40 s).

Entry 20 — 19 Oct 2026: lock bundle assembled

Bundle credit-impulse-realtime-prereg-v1.0-lock.zip: 42 files, 2,862,067 bytes, SHA-256 5da92075f7c13c94cc1fa6f47d8b00b81d21388349dc80d41b10acf0b63e3ba9.

It contains:

- this protocol, exported at Entry 19, as Markdown and PDF (44 pp.);
- all Phase 0–2 code, tables, the derived credit dataset, the Phase 1 results and the power and synthetic-test outputs;

- MANIFEST.txt, with SHA-256 for every file and for the raw public inputs not redistributed.

Final synthetic test (30 seeds, final code): no-effect rejection rates of 3% (P1a, P1b, P2a) and 7% (P3); planted-effect detection of 87%, 67%, 100% and 100%.

To lock: Andy publishes the bundle as GitHub release v1.0-lock, with Zenodo archiving enabled. The release URL, tag commit and DOI are then recorded in a new entry and in LOCK.json. From that point this protocol is frozen, and changes go to a dated deviation log.

Entry 21 — 19 Oct 2026: PROTOCOL LOCKED

Lock. Protocol v2.3 and the Phase 2 code are locked as a public GitHub release:

- **Release:** v1.0-lock, AndyMoran/credit-impulse-realtime-prereg, published 19 Oct 2026, 14:55 UTC
- **Tag commit:** 4eb084fb2c462fffec72574f108043ea9d796cc9 (signed by GitHub)
- **Zenodo DOI:** 10.5281/zenodo.23477871, as reported by Andy. The DOI page could not be checked from the workspace (rate-limited).

Verification. At the tag commit, MANIFEST.txt, code/phase2/phase2.py and protocol/protocol_v2.3.md were downloaded and their SHA-256 hashes match the assembled bundle exactly. The working copy of phase2.py is byte-identical to the locked one.

Note. The bundle zip (SHA-256 5da92075…) named in the release description does not appear among the release assets; only GitHub's two automatic source archives are listed. Its 42 files are committed individually at the tag, and their hashes are in the committed MANIFEST.txt, so the lock does not depend on the zip.

From this point: no edits to protocol v2.3, sections 1–14. Any change goes in a dated deviation log stating whether any results had been seen. LOCK.json has been written, and phase2.py may now run on real data, once. No real target or SPF error had been examined at lock.

Entry 22 — 19 Oct 2026: Phase 2 run (once) and results

Run. phase2.py (SHA-256 da697030…, identical to the locked copy) ran in real mode once, at 15:00:47–15:01:25 UTC, with exit code 0 and no deviations. Output: results.json SHA-256 9e4239dd116eaea7c9f65df83f85d349f338aeb4adb6ff16904a6793ed6fa99c, plus forecast tables for P1a, P1b, P2a, P3, S4 and E1.

Confirmatory core (all in the estimate-only band; RMSE ratio = credit model ÷ benchmark, below 1 means credit helps):

Test	Estimate	90% interval	Credible improvement?	Share of gain from 2007–10
P1a GDP, h = 4	ratio 1.106	0.984–1.356	No	total is a *loss* (−109); 68% of the loss is in 2007–10
P1b unemployment	ratio 1.011	0.994–1.043	No	total loss (−1.9)
P2a SPF GDP	ratio 1.025	0.988–1.076	No	total loss (−26.5); 5% in 2007–10
P3 GDP revisions	β_CI = 0.111 pp per CI point	−0.047 to 0.269 (wild block bootstrap)	No	—

Holm: no rejection (p = 0.555, 0.618, 0.665, 0.221). The P3 fixed-b HAC p-value (0.036) is shown for comparison only; under §9 as locked, the wild bootstrap governs.

Grid and S1. Primary cell (real-time credit, revised target): 1.106 for GDP and 1.011 for unemployment. Early-estimate target: 1.129 and 1.011. Revised-data benchmark: 1.106 and 1.003. Credit-revision premium: GDP +0.0005 (90% −0.066 to 0.037); unemployment +0.008 (−0.018 to 0.024). Both are **small** under the §4a rule.

Headline (§4a, pre-committed): "Null, small premium." *"Credit shows no detectable predictive content in either real-time or revised data at this sample size; the published evidence does not rest on revisions, and given that the available credit variation is concentrated in 2008–09, the design could reliably detect only very large gains, of roughly 40% or more."*

Detailed map. The row is "P1 null; premium small; S5 null" or "…S5 supported", depending on how S5 is read. S5 results are mixed:

- Contraction ADL for unemployment: ratio 0.957 (CW p = 0.002, unadjusted).
- Asymmetric ADL for unemployment: ratio 1.249.
- Both S5 specifications for GDP: ratios 1.053 and 1.055.

No S5 interval was pre-specified or computed. Reading to be recorded in the next entry.

Exploratory, uncorrected, about 30 comparisons (at 5%, about 1.5 false positives are expected by chance):

- S6, GDP: origins up to 2008Q3, ratio 0.959 (90% 0.896–0.982); from 2008Q4, ratio 1.522 (1.148–1.863).

- S6, unemployment: 1.004 before and 1.021 after.
- Unemployment signals from stock-based or real credit cycles:
  - S2 gap: ratio 0.922, p 0.002
  - S2 real credit growth: ratio 0.978, p 0.025
  - E1 Markov-switching: ratio 0.968, p 0.026
  - S4 BVAR: ratio 0.954, bootstrap p 0.077
  - S5 contraction: ratio 0.957, p 0.002
- None of these appears for GDP.
- P2b (SPF unemployment): ratio 1.115. P2a robustness with micro-data medians: ratio 1.026.
- R1 imputations: GDP 1.054 and 1.056; unemployment 1.001 and 1.000.
- Rolling 60-quarter window: GDP 1.243; unemployment 1.097.
- h = 1 and h = 2: ratios 1.02–1.03.
- Unemployment direction hit rate: AR(2) 66.2% vs ADL 64.9%.

D1 (descriptive; already seen before lock, Entry 17): in 2001 and 2007–08 both real-time signals were "late"; there were no hits. The CI signal was on in 29% of quarters.

No results were examined before this run apart from D1. Results are reported exactly as produced.

Entry 23 — 19 Oct 2026: S5 reading and final interpretive row

Decision (Andy, after the Phase 2 results were seen). S5 is recorded as **not supported**.

Reason. The protocol did not define "supported" for S5, and no interval was pre-specified. The results are mixed:

- Contraction ADL for unemployment: ratio 0.957.
- Asymmetric ADL for unemployment: ratio 1.249.
- Both S5 specifications for GDP: ratios 1.053 and 1.055.

No new interval or test is computed after the fact.

Final reading (§4a detailed map): "P1 null; premium small; S5 null". *No evidence of predictive content under real-time data at this sample size; only very large gains (roughly 40% or more) ruled out, because the credit variation is concentrated in 2008–09.* This refines, and does not override, the headline "Null, small premium" (Entry 22). Exploratory results (S2, S4, S6, E1) do not move the reading between rows.

Disclosure. This is an interpretive choice made with results in view. It is the conservative choice: the alternative row ("specification story") would have claimed more.

Entry 24 — 19 Oct 2026: §13 figures drawn from the locked outputs

figures.py reads results_real/ only and does no new estimation. It produces four figures, each as PNG at 300 dpi and as vector PDF:

- **Fig. 3:** the grid of RMSE ratios with 90% intervals (headline exhibit).
- **Fig. 4:** cumulative squared-error differences for P1a, P1b and P2a, with the 2007Q1–2010Q4 window and the crisis share.
- **Fig. 5:** the D1 threshold timeline.
- **Fig. 6:** GDP revisions against real-time CI (P3).

The line fitted in Fig. 6 is a bivariate fit, shown for display only; the reported estimate is the partial coefficient from §9. The two remaining §13 graphs are covered elsewhere:

- Real-time vs revised CI is Phase 1 Fig. 1.
- The k_o lag is constant at 2 at every origin, so it is stated in the text rather than drawn.

Palette checked with the validator (blue/orange; all checks pass). Hashes are in figures/SHA256.txt.

Entry 25 — 19 Oct 2026: independent check of the manuscript draft

A separate agent, without access to the drafting context, checked 77 claims in the working-paper draft against results.json, the forecast tables and the Phase 1 outputs. It recomputed derived figures from the raw files.

Result: 63 were OK, 9 wrong, 2 rounding, 3 unverifiable. Every confirmatory and exploratory estimate, interval, p-value, premium and count matched. The errors were in description:

- The pre-2008Q4 GDP gain was spread across 1999–2008 (origins 1999–2006 contribute 18.2 of 30.2), not "largely from anticipating the collapse".
- The losses fall on forecasts made in 2010–11 for 2011–12 (−135.6), not on forecasts of 2010.
- 2008–09 holds 72% of the impulse's squared deviations ("about three-quarters", not "almost all").
- The BVAR's credit variable is the impulse, not a slower-moving measure.
- "Contraction-asymmetric" was mislabelled; it should read "real-credit contraction".
- "Three documented breaks" contradicted "an undocumented units switch".
- Appendix A omitted the S3 drop.
- "Every possible conclusion" overstated what was locked.
- Rounding: a detection rate of 29–40%, not 30–40%; the BVAR p-value is 0.078.

Claude confirmed the main items independently (pre-2008Q4 split 18.2 / 12.1; peak at the 2008Q2 origin; −135.6 for origins 2010Q1–2011Q4; 72% share), and all corrections have been made in the draft. The unverifiable items were checked against the code: flows are divided by 4 (build.py and protocol §7), and the current release is dated 11 Sep 2026 (build.py). One item is interpretive and stays as such: that 2001 was not a credit recession. None of the corrections changes a number in the results or the pre-registered reading. Report: check/verification_report.md.

Entry 26 — 19 Oct 2026: manuscript revised after external feedback

Andy supplied written feedback (a new abstract, a §4.2 paragraph, a new §6 and §7, and the Keen (2013) reference). It was adopted with corrections; no result or pre-registered reading changed.

Corrections made:

- Four errors the feedback reintroduced were kept out, as Entry 25 had established:
  - "catching the collapse" / "anticipated the downturn";
  - "impulse stayed negative through the recovery";
  - "almost all" of the variation;
  - the BVAR grouped with stock measures.
- Two claims were narrowed:
  - "first complete real-time record" became "a complete real-time record";
  - "the standard transformations" became "the credit impulse".
- "Did not share a common causal basis" was reworded as a non-causal description.

The Keen discussion moved to a labelled §6.1, *Discussion beyond the pre-registered map*, because the protocol bars post hoc explanation inside the map. "Rejects" was replaced by interval language: the 90% intervals exclude average gains above about 2%, 1% and 0.6%. The claim that the unemployment leads support the credit-accelerator view was replaced by its opposite, which the data show: the leads came from stock measures, and the impulse itself did not help unemployment.

Extensions in §7 are each marked as needing their own preregistration. Adrian, Boyarchenko and Giannone (2019) and Keen (2013) were added to the references, both marked †.

Entry 27 — 19 Oct 2026: results release v2.0-results published

Release. v2.0-results, commit 27fab0ba9835b1b1b97e95c49b11abb88ec17a0a, published 19 Oct 2026 at 16:42 (time zone as shown by GitHub).

Verified from the workspace:

- MANIFEST_v2.txt at the tag is byte-identical to the assembled bundle.
- The hashes of results.json (9e4239dd…), DEVIATIONS.md, the manuscript PDF and Fig. 4 match.
- The attached zip downloads with SHA-256 f2d22c08…, matching the bundle, so the v1.0 gap (zip not attached) does not recur.
- At tag v1.0-lock, phase2.py still hashes to da697030…; the locked files are untouched.

Zenodo. The v2.0 version DOI is not yet recorded; it will be added when available.

Zenodo update (19 Oct 2026). v2.0-results is archived as 10.5281/zenodo.23479717, as reported by Andy. That is a new version under the same Zenodo record, and the preregistration keeps its own DOI, 10.5281/zenodo.23477871.

Entry 28 (19 Oct 2026): red-team review of the manuscript (results seen)

An external red-team review of the working-paper draft was adopted, and no estimate, test, sample or decision rule changed. The changes were:

- **Title.** Narrowed to "Did the Credit Impulse Help Forecasters in Real Time? A Preregistered Test, 1999–2019".
- **Overclaims softened.** The archive is now described as complete and machine-readable for 1999–2019. The GDP bound is about 1.6% (from "about 2%"). The machine-learning sentence was softened, and the 2001 downturn is described as "not generally treated as credit-driven in this literature".
- **Definitions added.** Hybrid 1990s vintages, D2, the credit-revision premium, the cumulative gain (with a new Table 5 of period totals), "specification story", and GS2 quarterly averaging.
- **Interpretation added.** The difference between the power calculation and the realised interval; why the SPF correction loses from the start; the rolling-window instability; a growth-at-risk preview; and the denominator caveat on the gap's exploratory gain. Two scope points: financial-sector credit is excluded, and the credit data are two quarters staler than output (the ragged-edge fills, R1, did not help). The Section 6.1 episode-specific reading now notes that only 12.1 of the 30.2 pre-2008Q4 gain came from 2007Q1–2008Q3.
- **Appendices B and C.** B gives the S4, E1 and R1 specifications as in the protocol; C points to the release-date, origin and vintage files.
- **Citations.** Repullo and Saurina (2011) is now cited; Gilchrist and Zakrajšek (2012) and Harvey, Leybourne and Newbold (1997) were added after checking against publisher records.

Two review claims were checked and rejected. First, the Section 5.3 arithmetic is consistent: the period totals +18.2, +11.6, −135.6 and −3.1 sum to the total of −108.9, and Table 5 now shows this. Second, GS2 enters both BVAR variants, so the BVAR comparison isolates credit, and the text now says so. The duplicated figure captions in the Markdown export were my error and have been removed.

Entry 29 (19 Oct 2026): second external review; post-lock checks (results seen)

A second external review was assessed point by point. Three post-lock checks were run. None re-estimates or replaces a confirmatory quantity. The scripts are in `p2/post_lock/` and import the locked `phase2.py` unchanged.

- **Interval coverage** (`coverage.py`). Outcomes were simulated with the real credit path: 300 replications at three effect sizes, using the locked block bootstrap. Nominal 90% intervals for the P1a ratio covered the true ratio 80% of the time over the full sample, and 74–83% in the S6 halves. With no credit effect, the full-sample interval fell wholly below 1 in 1% of replications and the pre-2008Q4 interval in 5%; a true effect did not raise the pre-2008Q4 rate (4–7%). The manuscript no longer treats the favourable interval ends (1.6%, 1.2%, 0.6%) as firm bounds.
- **P1a coefficient paths and the largest losses** (`diagnostics.py`, Figure 7). The locked specification was re-run, and its forecasts match the locked run exactly. The four credit coefficients sum to between −0.17 and −0.28 up to 2010 and to about −0.10 by 2018. The 2010–11 losses came from forecasts of 5.4–7.5% growth, a rebound driven by the deeply negative impulse. **This corrects an error in the draft**, which said the model "kept forecasting weakness into the 2011–12 recovery". That statement had not been checked against the forecasts and was the opposite of what happened.
- **P2a training start.** On 68 common origins the ratio is 1.019 with the locked 1990Q3 start, 1.130 from 1993Q1 and 1.095 from 1996Q1. A shorter training sample does not favour credit.

Two of the review's claims were rejected:

- The review said P3 was "computed, then switched". In fact the wild bootstrap was adopted in Entry 19 before lock, and both p-values were first seen in the single run.
- The review called S6 post-hoc. S6 is pre-specified (protocol §7).

Two literature citations in the review were garbled: Drehmann et al. is 2010, not 2017, and "Policymakers' GAIT" was not found (Aikman, Haldane and Nelson, 2015, was cited instead). A third, "Biggs and Mayer (2013)", could not be found and was not cited.

Adopted: wording changes ("preregistered evaluation with a null result"; "illustrate" rather than "document" for the power lesson; "on average" in the introduction); a lock-and-run timeline in Appendix A; the P3 size evidence next to its 0.036 p-value; the D1 rule and

episode start dates in the text; a binomial note on the exploratory multiplicity; the full results hash; and a clearer premium definition. A paragraph on the 2019Q4 endpoint was also added. It discloses that the protocol checklist promised to report 2020–21 separately, which has not yet been done. Tables were renumbered (4 ↔ 6, new Table 5); Figure 7 is a new post-lock figure.

Entry 30 (19 Oct 2026): coverage-calibrated intervals (results seen)

The reviewer's follow-up argued that wording alone was not enough: intervals known to undercover should be reported alongside corrected ones. We did this with `calibrate.py` and `calibrated_intervals.py` in `p2/post_lock/`. They use synthetic outcomes on the real credit path, 300 replications at each of two effect sizes, with the locked bootstrap seed, draws and block length.

- **Coverage of the locked 90% intervals:** P1a 80–81%, P1b 74–75%, P2a 69–77%. The misses are one-sided, and the side depends on the effect: with no effect the intervals sit below the truth, and with an effect above it. Raising the percentile level does not fix this; at 99% coverage is still only 86–96%.
- **Method adopted:** widen the locked 90% interval about the point estimate by the smallest factor that gives at least 90% coverage at both effect sizes. The factors are 1.35 for P1a, 1.75 for P1b and 2.1 for P2a. Applied to the locked outputs, they give P1a 0.941–1.443, P1b 0.981–1.067 and P2a 0.948–1.132. None shows a credible improvement. The locked 90% intervals were reproduced exactly before widening.
- **S6 pre-2008Q4 half:** the factor is 1.35, giving 0.874–0.990, still below 1. With no credit effect, a widened pre-2008Q4 interval lies wholly below 1 in about 3% of replications.
- **Status:** the locked intervals still govern the pre-registered "credible improvement" rule, and the calibrated intervals are reported alongside in Table 3b. The interval method was not switched after results were seen, because that would be a post-hoc change to the decision rule. P3 is not recalibrated: its wild bootstrap's size was checked before lock.
- **Text:** the S6 discussion now states both limits. The undercovering intervals make the result look cleaner than it is, and the quarters entering pre-2008Q4 forecasts hold only about 14% of the impulse's squared deviations, so the design could not detect a pre-crisis effect. The second is a limit of the design, not evidence of absence. The design lesson now cites Hansen (2000) and Loh (1987) and claims no priority.
- **Record correction:** in replying to the review I said P2b was missing from the draft. It was reported, in one sentence of Section 5.4, without interpretation; an interpretation has since been added. The response to reviewers should not describe it as an omitted output.

Entry 31 (19 Oct 2026): author-run cross-platform re-run (results seen)

This is a check of portability, not the independent third-party re-run, which is still outstanding: it was run by the author, on his own machine.

- **Setup.** Windows 11, Python 3.13.14, numpy 2.3.3, pandas 2.3.3, scipy 1.18.1, statsmodels 0.15.0. The published run used Linux, Python 3.13.16, numpy 2.5.3 and pandas 3.0.5.
- **Method.** The script `verify_lock.py` (written for the third-party check) was run at 19:20 UTC on 19 October 2026. Its inputs were the `v1.0-lock` and `v2.0-results` source archives downloaded from GitHub, and `raw_inputs_v1.0-lock.zip` (SHA-256 `56ec8466dd5ba9986a82020323327af1c497f91e573c2b5c3ae327c95c87a6f3`).
- **Checks before the run.** All 41 release files matched `MANIFEST.txt`. `phase2.py` matched the locked hash, all ten raw inputs matched their recorded hashes, and `LOCK.json` named the locked commit and DOI.
- **Result.** The analysis ran once, in 43 seconds. The new `results.json` (SHA-256 `8f73920a8e53ccd7876a0e4abf3aeadd9a6078f4d65091555fa75ce00f868736`) differs from the published file only in floating-point rounding, in the 15th–16th significant digit. Every confirmatory estimate, interval and p-value, and every Holm decision, matched within the 0.0005 tolerance, with the p-values identical. Verdict: PASS. The report is `verification_report_PASS.txt`.
- **Script fixes during this check.** Two problems were found and fixed before the passing run:
  - The script now locates the release and results folders inside the unpacked archives.
  - It no longer starts the analysis in Python's isolated mode (`-I`). On Windows that mode hid user-installed packages, and the first attempt failed before any computation. The analysis now runs with `-E -P`.
  - Neither fix touches the locked code. The final script reproduced the published hash exactly in the Linux environment.

Entry 32 (19 Oct 2026): second independent check of the manuscript (results seen)

An agent that had not seen the drafting checked 171 claims in the revised manuscript against the locked and post-lock outputs, recomputing each in Python (report: `check/verification_report_v2.md`). The result was 157 OK, 8 wrong, 2 rounding and 4 unverifiable. Every estimate and table value matched. The check confirmed the corrected mechanism of Entry 29: the credit model over-forecast GDP growth at all eight origins from 2010Q1 to 2011Q4.

Corrected in the manuscript:

- **§6.1.** The lead from credit to target is six to nine quarters, not four to six. The lags run back from $q^* = o - 2$, and the target is $o + 4$.

- **§5.4.** P2b is pre-registered as *exploratory*, not secondary (protocol §7 table).
- **Introduction.** "Rather than concentrated in the collapse" overstated the point: about 40% of the pre-2008Q4 gain (12.1 of 30.2) came from 2007Q1–2008Q3.
- **§5.1.** Raising the percentile level does restore coverage for GDP, at 97%. It fails only for unemployment and the SPF correction, which reach 86–93% even at 99%.
- **Coverage rates.** The full-sample false-positive rate is about 1–2% (0.7% and 1.7% in the two simulations), not 1%. This also corrects Entry 29.
- **Coefficient range.** The coefficient sum up to 2010 is −0.16 to −0.28, not −0.17 to −0.28 (rounding).
- **Appendix A** now cites Entries 1–31.
- **Data availability** now lists all the post-lock scripts.
- **Appendix C.** The release-date file covers 95 releases, of which 83 are used.
- **§5.3.** The credit model leads from the first origin, 1999Q3, not from 2000.
- **Figures.** Figures 1, 2, 3 and 5 are now cited in the text, and Figure 5's "late" label is tied to the rule's own classification.

Not changed:

- Figure 7 is cited before Figures 5 and 6. This keeps the pre-registered §13 figure numbers.
- Four claims are unverifiable from the files: the hand check of the June 1999 vintage (Entries 2–3 record it); the date on which §10 was written (the protocol version is dated 17 October); the "bounce-back" interpretation, which is labelled as interpretation; and the existence of Entries 27–32 (they are in this log).

Entry 33 (20 Oct 2026): pandemic-period plan frozen (no 2020 data seen)

The analysis plan for the non-preregistered 2020–21 illustration and its script were committed and tagged before any 2020 Z.1 release was downloaded.

- **Commit** `b9a7fc094bb895d9912c2953203b0037e40030f9`, tag `pandemic-plan` (GitHub release of the same name), about 08:58 UTC on 20 October 2026.
- **Files.** `pandemic/PLAN.md` (SHA-256 `bd50d8b1ea81fef2a6c3a822c5d18c633aa4f73806853421a8fe3273a338c03f`) and `code/post_lock/pandemic.py` (SHA-256 `759dbf4fbbb6b4084ed513ead60e8649500e4c16a034f263407be55657862ed6`). Both were fetched back from GitHub at the commit and at the tag, and both match. Recorded in `pandemic/PLAN_LOCK.json`.
- **Tests before freezing.** These used locked data only. Check mode reproduced all 234 locked P1a, P1b and P2a forecasts exactly. A synthetic test, with fake 2020 credit files and simulated outcomes, confirmed that each 2020 origin selects its release with k = 2.

No real 2020 credit data and no 2020–21 forecast had been computed.

- **Next steps (plan §5, steps 4–7):** download and hash the March, June and September 2020 Z.1 releases and the two release-dates files; parse them with the locked parser; run once.

Entry 34 (20 Oct 2026): 2020 data downloaded, hashed and parsed (no forecast computed)

This covers plan §5, steps 4–5, carried out after the `pandemic-plan` tag. The author downloaded the files on his own computer and hashed them there with `Get-FileHash` before any was opened. They were then copied to the analysis workspace, re-hashed, and matched.

File	SHA-256
fed_z1_release_dates.htm	`821f06eeb2c9e1011dd77eb49b8e91efb6425de5daf8dff7ebef39cc6156154a`

z1_20200921.zip	`5591241ad6d0d0297b660d1225955cec715adf21ab6f918e2674a66a1980ad9d`

- **Release dates.** From the Federal Reserve page: 12 March, 11 June and 21 September 2020. All fall before their origins (15 May, 15 August and 15 November 2020).
- **Parsing.** The locked `parse_z1.py`, hash `1acb4b84…` matching `MANIFEST.txt`, ran unchanged and found 3 vintages OK, 0 flagged. The last quarters are 2019Q4, 2020Q1 and 2020Q2, and the series codes are the same four as in December 2019.
- **Continuity.** The median level ratio for each of the three consecutive pairs (Dec 2019 to Mar 2020, Mar to Jun, Jun to Sep), for both levels, is 1.000.
- **SPF deadlines.** The four 2019 deadlines in the downloaded file match the locked map. The 2020 deadlines are 11 February, 12 May, 12 August and 10 November, so k = 2 at every 2020 survey.
- **Run inputs.** `credit_vintages_2020.csv` (`db47281b…`), `download_log_2020.csv` (`ccafdcd5…`) and `spf_deadlines_2020.csv` (`e34505d5…`).
- **Fixes.** No mapping fix was needed.

No forecast for any 2020–21 target had been computed at this point.

Entry 35 (20 Oct 2026): pandemic-period run (results seen)

This is plan §5, step 6. `pandemic.py` (hash `759dbf4f…`, matching the tag) ran once in real mode with the locked `phase2.py` and exited with code 0. Outputs are in `pandemic/results/`; `pandemic_results.json` has SHA-256 `5ec29ad9c9b0ba1aef9af26c632b8381075dcf7ad337b8a2948fd62129abcfd7`.

Test	Ratio over the eight targets	Band (plan §4)	Extended ratio, origins 1999Q3–2020Q4	Locked ratio, 1999Q3–2018Q4
P1a GDP	0.992	about as accurate	1.014	1.106
P1b unemployment	0.910	about as accurate	0.925	1.011
P2a SPF	0.999	about as accurate	1.004	1.025

Two features of the output were noted on first reading, before any text was written:

- **One forecast drives the P1b ratio.** At origin 2020Q3, both models were trained on data that include the 2020Q2 jump in unemployment, and both extrapolated it for 2021Q3: the benchmark forecast 26.0% and the credit model 23.8%, against an outcome of 5.1%. That target contributes −88.8 of the eight-target squared-error difference.
- **The pandemic errors dominate the extended ratios.** The pandemic targets' squared errors (for GDP, outcomes of −28.0% and +34.9% annualised) dwarf those of 1999–2018, so both models' extended ratios move towards 1.

The plan's pre-written sentences do not mention either point. Whether to add an explanatory note, which would be a disclosed deviation under plan §6, is for the author to decide.

Entry 36 (20 Oct 2026): pandemic-period results written up; declared deviation (results seen)

This is plan §5, step 7. Section 5.6 and Table 7 were added to the manuscript. They use the plan's pre-written sentences for each test (all three ratios fall in the 0.90–1.10 band), the direction-of-error sentences, and the extended-sample sentences. There is one sentence in Section 6, and the abstract, headline and interpretive map are unchanged.

Deviation (plan §6: wording other than the pre-written sentences). At the author's decision, an explanatory note was added after seeing the results. It covers the two features recorded in Entry 35:

- one forecast (P1b, origin 2020Q3) decides the unemployment ratio;
- the scale of the pandemic errors pulls the extended-sample ratios towards 1.

The reason is that the pre-written sentences alone would invite the reading that credit improved unemployment forecasts, or that the full-sample GDP loss shrank because credit did better. The note is labelled as a deviation in Section 5.6 and in Appendix A.

A closing paragraph also reports the 2020 real-time impulse and the size of the credit terms, all taken from the run's outputs. Nothing else in the plan was changed, and no further analysis was run.

Entry 37 (20 Oct 2026): third external review adopted (results seen)

The review's points were adopted in full, and no estimate changed. The changes:

- **Headline language.** The abstract, introduction and conclusion now say "no convincing average gain", while noting that the uncertainty still allows modest gains of up to about 6%. They also say that low power does not rule out smaller gains. The pre-2008Q4 split was removed from the abstract. In the introduction it is now described as fragile, with the design's inability to identify a pre-crisis effect stated first.
- **Calibrated intervals.** Table 3b is relabelled a post-lock sensitivity analysis and is no longer called "the better guide to precision". The text states its limits: one simulated data-generating process; two effect sizes, chosen after the results were seen; 300 replications each; and no alternative error processes or bootstrap schemes. A new Appendix D gives the full inference settings (fixed-b, block bootstrap, wild bootstrap, Holm) and the simulation design, seeds and factor search.
- **Training vintages, checked against the locked code.** At each origin the estimation sample uses that origin's RTDSM vintage for GDP and unemployment, and the latest Z.1 release for the whole credit history. This is end-of-sample-vintage estimation. §4.2 now says so, cites Koenig, Dolmas and Piger (2003), and states that the alternative, estimating each training pair on its own historical vintage, is not tested. It also adds a worked timing example for origin 2010Q3, checked against the locked origin table: the 10 June 2010 release, q* = 2010Q1, training targets up to 2010Q2, target 2011Q3.
- **Scope.**
  - The dataset is labelled "household and nonfinancial business credit", not "US private credit".
  - The benchmark is stated as a direct AR(2), not the best available models.
  - The SPF exercise is described as one additive correction.

- The §6.1 sentence linking the coefficient sign to a demand channel was replaced by one stating that the coefficient path explains a forecasting-model failure only.

Outstanding: the independent third-party re-run, and publication of the post-lock scripts in v2.1.

Entry 38 (20 Oct 2026): release v2.1 published

Release v2.1 is at commit `2510c83567fcf7b01118709d5ec95cd656da40bb` (Zenodo DOI 10.5281/zenodo.23497087). It contains:

- the revised working paper (v2.1) and Figure 7;
- the post-lock scripts and outputs;
- the pandemic-period folder;
- the verification kit (`verify_lock.py`, `VERIFY.md`, and the author's cross-platform re-run);
- an issue template for reporting re-runs;
- `REPLICATION.md`, a journal-style replication README;
- `DEVIATIONS.md` and the audit log through Entry 37.

The bundle zip and the raw-input zip were to be attached to the release. The raw-input zip holds the ten Philadelphia Fed and FRED files, SHA-256 `56ec8466…a6f3`. It is distributed for verification, which is a use the Real-Time Data Set page explicitly permits.

Checked against the commit. Every file was fetched from GitHub at the commit and hashed. Of 48 files, 46 match `MANIFEST_v2.1.txt`. The other two differ as expected:

- `REPLICATION.md`, because the author completed its raw-input sentence ("attached to v2.1 release");
- the issue template, which was re-committed.

A corrected `MANIFEST_v2.1.txt` gives the hashes as committed. The copies of these two files inside the attached bundle zip are the pre-edit versions.

Release checks, completed 20 October. The release tag is `v2.1-verification`; an earlier check under the name `v2.1` failed for that reason. Both attached assets were downloaded from the release and hashed. They match exactly: `credit-impulse-v2.1.zip` (`19e7e367…e51c`) and `raw_inputs_v1.0-lock.zip` (`56ec8466…a6f3`). The files at the tag match the commit. The Zenodo record could not be opened from the analysis workspace because doi.org rate-limited the request; the author reports DOI 10.5281/zenodo.23497087 for this release.

The manuscript's data-availability statement now cites v2.1 and its DOI. The PDF inside the release predates this citation, because a release cannot cite its own DOI.

Entry 39 (20 Oct 2026): style rewrite of the manuscript (results seen)

At the author's request, the manuscript was rewritten in place following Strunk and White and Zinsser, as a line edit plus restructure.

- **Voice.** First person singular replaces "we".
- **Restructure.** The repeated power and coverage caveat is now stated in full once, in §5.1. The §5.3 paragraph is split into three labelled parts. §6's five qualifications and its "what the results do not say" paragraph are merged into four limits.
- **Effect.** The paper is version 2.2 (in revision). Prose fell from 8,620 to about 8,250 words, sentences over 35 words from 49 to 35, and passive constructions from about 88 to about 58.

Protected and checked by script against the v2.1 text:

- the pre-committed headline sentence, the final-reading sentence and the three pre-written pandemic-period sentences, all word for word;
- all ten tables, byte for byte;
- the set of numbers, with no new number introduced.

Appendices B–D and the references were not edited.

Meaning check. An agent that had not seen the editing compared the two versions claim by claim. Its first pass found eleven meaning changes and no numerical ones. The changes were:

- the AI-use sentence had come to overstate the author's own role;
- several hedges had been dropped or softened ("very large average", "in a sensitivity analysis", "about", "exploratory", "conditional on the realised path");
- §6 contained an untested claim ("fits such a sample poorly");
- one cross-reference was wrong;
- some referents were vague.

All eleven were corrected. A re-check confirmed them resolved and found two small problems introduced by the fixes (the contributions count and an unclear "which"), both corrected. The report is `rewrite/meaning_check.md`. No result changed.

Entry 40 (20 Oct 2026): terms box added (results seen)

At the author's request, Box 1, "Terms used in this paper", was added at the end of §1. It defines seventeen terms in plain language, each taken from the paper's own definitions. It adds no claim and no number. The protected passages, tables and numbers were rechecked by script after the insertion. No result changed.

Entry 41 (20 Oct 2026): abstract and introduction revised after reader feedback (results seen)

The changes follow written feedback on the abstract and introduction:

- **Abstract rewritten.** It now opens with the question and its motivation, defines the credit impulse, explains why the AR(2) benchmark was chosen, and gives the GDP result as "worsened … by 10.6% on average", wording already used in §5.1. The design lesson has its own paragraph, and one sentence reports the exploratory unemployment leads. Only the GDP estimate keeps its interval.
- **"About 50%" replaced by "52% higher"** in the abstract and in §1 finding 2. This is the RMSE of the S6 post-2008Q4 split relative to the benchmark (ratio 1.522); the new figure is a rounding of that existing ratio.
- **Table 3 note.** The claim that the fixed-b P3 p-value is invalid is now joined to its reason by a colon.
- **§6.** The introduction to the locked headline now reads "the headline for the confirmatory family is". The locked sentence itself is unchanged.
- **§5.6.** A clause notes that the pre-written sentences are reproduced word for word, so their repetition is deliberate.

Two suggestions were declined. Editing the locked headline sentence would breach the protocol. The suggested phrase "nearly all" of the forecasting evidence overstated what the paper establishes ("much of").

The protected passages and tables were rechecked by script and are unchanged. No result changed.

Entry 42 (20 Oct 2026): style-sheet pass (results seen)

A reader's style sheet (positive form, no hedging adverbs, active voice, no "there is/are", concrete verbs, emphatic endings) was applied to the abstract, §1, §2, §4, §5, §6 and §7:

- "Did not improve" and "essentially unchanged" are replaced by the estimates: RMSE up 1.1% for unemployment and 2.5% for the SPF correction.
- "Did not predict revisions" becomes "no response of GDP revisions to the impulse is detectable", with the estimate and interval in the abstract.
- "Modest gains" and "gains of a few per cent" become "gains of up to about 6%", the Table 3b figure.
- "Slightly" before 2008Q4 becomes "about 4%", the S6 figure already in §1.
- D1 now reads "the impulse rule flagged both recessions late, and the credit-growth rule flagged neither".
- "Corrupts" becomes "biases".

- The "there is/are" sentences and the passive lock sentence in the abstract are rewritten.

Uncertainty statements were kept, as the style sheet asks: interval language, "leads, not findings", the power statement and "cannot exclude gains of up to about 6%". The style sheet's "the grid covers 78 origins" was not used, because "grid" already names the 2×2 design; the sentence reads "The sample has 78 forecast origins". The protected passages and tables were rechecked by script and are unchanged. No new number was introduced. No result changed.

Entry 43 (20 Oct 2026): GDP result given more prominence (results seen)

At the author's request, the abstract and §1 now lead with the point estimate. Both open their results with "Adding the real-time credit impulse made forecasts worse", followed by the 10.6% GDP result, and finding 1's label is now "Worse forecasts on average". Each is followed at once by a caveat: the interval admits a small improvement, and the single-cycle sample cannot rule out one of up to about 6%.

The power sentence now reads "could reliably detect only a large improvement, one that cut forecast errors by roughly 40%", because the author misread "gains of roughly 40%" as growth in output. For the same reason, Box 1's RMSE-ratio entry now defines a gain as a fall in forecast error.

The locked sentences are unchanged, and "worse" describes the point estimate only. The protected passages and tables were rechecked by script. No new number was introduced. No result changed.

Entry 44 (20 Oct 2026): claims bounded after reader feedback (results seen)

Three changes follow reader feedback.

- **The 2011–12 forecasts.** "A recovery that never came" is replaced in the abstract, §1 and §7 by "a sharp rebound that did not materialise". §1 adds that growth resumed, but far more slowly than forecast. The outcomes in Table 5 are positive in most cases, so the old wording overstated the miss.
- **Headline bounded.** The abstract now opens its result with "Over this sample". §5's opening statement of the 10.6% result now carries the caveat that an improvement of up to about 6% cannot be ruled out (Table 3b), as the abstract, §1 and §7 already did.
- **Methodological lesson scoped.** The abstract, §1 (contributions), §2 (methods), §4.4 and §7 now state that the power and coverage problem is shown for one predictor path and one simulated process, and that generalisation is untested. §7 extension 3 now names other clustered paths and error processes as the study needed.

The protected passages and tables were rechecked by script and are unchanged. No new number was introduced. No result changed.

Entry 45 (20 Oct 2026): working paper v2.2 prepared for posting (results seen)

The paper's abstract is replaced by a 183-word version for repository listings. It keeps the 10.6% GDP result with its interval, the caveat that an improvement of up to about 6% cannot be ruled out, and the methods lesson scoped to this predictor. The fuller statements stay in §1. The title-page line now gives the author as an independent researcher and lists the DOIs of the locked, results and v2.1 releases.

The PDF (A4, 33 pages, seven figures) was exported from the manuscript for posting to SSRN and MPRA, and for a v2.2 release on GitHub and Zenodo. The protected passages and tables were rechecked by script and are unchanged. No result changed. Posting dates and identifiers will be recorded when known.

Entry 46 (20 Oct 2026): concrete-language pass (results seen)

At the author's request, a full pass through §1–§7 replaced abstract phrasing with concrete statements, and applied his style guide: positive form, numbers in place of hedging adverbs, active voice, no "there is/are", precise verbs and emphatic endings.

- **Opening.** The abstract and §1 now ask whether credit could improve on a simple autoregressive forecast, and answer "On the 1999–2019 evidence, no". In the same sentence they add that a gain of up to about 6% cannot be ruled out.
- **Tense.** The abstract now says "rebuilt" and "ran", matching §1.
- **Replaced phrases.** "Useful", "carry information" and "usable as published" now say what the tests measure: whether credit improved forecasts or predicted revisions.
- **Main text.** Passive and nominalised sentences in §3–§5 were rewritten in the active voice.

An independent agent then compared the text before and after, claim by claim. It found 15 meaning changes and no changed results. All 15 were corrected or reverted:

- the caveat moved next to the "no";
- "no credible gain for any target" restored in §1;
- the conclusion restored to "no better than", with the point estimates labelled and "every interval includes no change";
- "fixed coefficients" corrected, since the models are re-estimated at each origin;
- "roughly 40% or more" restored;
- "is not a general cure", "does not help credit" and "was not stable either" restored, because the new wording claimed more than the numbers show;

- the SPF target wording corrected;
- "offset" used for the widened intervals, which are not repaired intervals;
- "modest" kept for credit-flow revisions;
- "would be expected to produce" used for the multiplicity count.

The agent could not verify two statements from the paper alone: "Entries 1–45", which this log confirms, and the statement that the paper is in release v2.2, which becomes true when that release is published. The protected passages and tables were rechecked by script and are unchanged. No result changed.

Entry 47 (20 Oct 2026): abstract power sentence reworded (results seen)

At the author's request, the abstract's power sentence now reads: "About three-quarters of the impulse's variation occurred in 2008–09; on that realised path, the test reached 80% power only when credit truly cut forecast RMSE by about 40%, a true RMSE ratio of about 0.6." The wording follows §4.4 (72% of squared deviations; 80% power at a ratio of about 0.6). Appendix A no longer gives an entry count for the log, which changes with each release; it now says that the full log is published with each release. No result changed.

Entry 48 (20 Oct 2026): abstract rewritten as a plain-language summary (results seen)

At the author's request, the abstract now serves as an executive summary and leaves technical terms to the body of the paper.

- **Power.** The sentence now reads: "the test would reliably detect a benefit from credit only if it shrank forecast errors by about 40%". This replaces "80% power" and "RMSE ratio of about 0.6".
- **Removed from the abstract.** The RMSE ratio and 90% interval are gone. The opening caveat, that a gain of up to about 6% cannot be ruled out, still states the uncertainty, and Table 3 and §1 keep the figures.
- **Methods lesson.** It now says, in plain terms, that standard methods overstated how sensitive the test was and how precise its results were.
- **"Preregistered".** It is explained in a few words: the plan and code were published before any forecast was scored.

The protected passages and tables were rechecked by script. No result changed.

Entry 49 (22 Oct 2026): opening answer clarified; abstract split into paragraphs (results seen)

At the author's request, "On the 1999–2019 evidence, no, though a gain of up to about 6% cannot be ruled out" is split in the abstract and §1 into a verdict and its evidence: "On the 1999–2019 evidence, no. The best estimate is that [credit / adding the real-time credit impulse] made forecasts worse [§1: 10.6% worse], though with only one credit cycle in the data a small benefit, of up to about 6%, cannot be ruled out." In §1 the following sentence is merged so the 10.6% is not repeated.

The abstract is now in three paragraphs: the question and answer, what was done and found, and the limits and methods lesson. The wording is otherwise unchanged. The protected passages and tables were rechecked by script. No result changed.

Entry 50 (22 Oct 2026): motivation sentence added to the abstract; version date updated (results seen)

At the author's request, the abstract's second paragraph now opens with the motivation from §1: "Much of the evidence that credit matters for the business cycle comes from revised data, which no forecaster had at the time." The version date on the title page and in the file names is now 22 October 2026. The protected passages and tables were rechecked by script. No result changed.

Entry 51 (22 Oct 2026): placement of the 6% caveat clarified (results seen)

At the author's request, the abstract and §1 now say that a small benefit of up to about 6% "lies at the edge of what the data allow" and cannot be ruled out. The previous wording gave the benefit equal weight with the best estimate.

The author's suggestion of "unlikely" was not adopted. The intervals are frequentist and known to undercover (§5.1), so they do not support a probability statement about values inside them. No result changed. The protected passages and tables were rechecked by script.

Entry 52 (22 Oct 2026): range of plausible effects stated in the abstract and §1 (results seen)

At the author's request, the abstract and §1 now give the GDP result as a best estimate plus a range, replacing "lies at the edge of what the data allow". The abstract gives the widened range (about 6% better to 44% worse). §1 adds a three-row table: best estimate 10.6% worse; locked 90% interval from about 2% better to 36% worse; interval widened to offset its undercoverage from about 6% better to 44% worse.

The percentages are the Table 3 and Table 3b ratios restated: 1.106, 0.984–1.356 and 0.941–1.443, with 0.984 rounded to "about 2% better". The 10.6% in the abstract's second paragraph is folded into the first, so it is not repeated. The protected passages and tables were rechecked by script. No result changed.

Entry 53 (22 Oct 2026): credit-to-GDP gap defined in §1 (results seen)

At the author's request, the §1 sentence on Edge and Meisenzahl (2011) now defines the gap in plain words: how far the ratio of credit to GDP sits above its long-run trend, a measure regulators use to set banks' capital buffers. It also says what the size of the revisions means: the first readings said little about the gap's final value. The protected passages and tables were rechecked by script. No result changed.

Entry 54 (22 Oct 2026): Edge and Meisenzahl sentence reworded (results seen)

At the author's request, the §1 sentence was reworded again. It now defines the gap in its own sentence: how far credit, relative to GDP, has risen above its long-run trend, used by regulators to decide when banks must hold extra capital. It states the consequence of revisions as large as the first reading: enough to turn "on trend" into "well above trend", or the reverse. No result changed. The protected passages and tables were rechecked by script.

Entry 55 (22 Oct 2026): abstract reorganised (results seen)

At the author's request, the abstract's first two paragraphs were reorganised so that each holds one idea.

- **First paragraph: all the results.** It gives the question, the answer, the GDP best estimate and range, the 1–3% results for unemployment and the SPF, the finding that revised data did no better, and the misread rebound.
- **Second paragraph: what was built and why.** It gives the motivation, the dataset, the impulse and the preregistration. The long sentence there is split into three.

The third paragraph is unchanged, and so is the wording of every result. The protected passages and tables were rechecked by script. No result changed.

Entry 56 (22 Oct 2026): reader feedback on power, timing and references (results seen)

Two sets of reader feedback were adopted in part.

- **Power versus uncertainty.** The abstract now adds that smaller benefits, such as the 6% the data still allow, could easily have gone undetected, so the 40% detection threshold is not read as ruling out gains below 40%. §6 now precedes the refinements

of the locked headline with a plain statement: the study found no improvement but is too underpowered to rule out modest gains. §7 now says the same, giving both figures. The locked headline sentence is unchanged.

- **Timing.** Box 1′s horizon entry now states the convention. The target is four quarters after the forecast origin, as in the SPF, so the comparison is like for like. Because GDP is published with a lag, the target lies five quarters after the latest GDP figure.
- **Gap wording.** The credit-to-GDP gap is now described as "a guide for setting countercyclical capital buffers", replacing "regulators use it to decide when banks must hold extra capital", which overstated how automatically it is used.
- **References.** Barnichon and Nekarda (2012) now gives the volume, issue and pages (43(2): 83–131), checked against RePEc. The Edge and Meisenzahl page range was not added, because neither the IJCB page nor the search results confirmed it. DOIs were not added across the list, because they could not be verified from this environment; adding unverified DOIs would risk introducing errors. The Biggs, Mayer and Pick in-text citation points to the 2009 working paper, as intended.

The protected passages and tables were rechecked by script. No result changed.

Entry 57 (22 Oct 2026): framing feedback adopted (results seen)

Reader feedback recommended keeping the preregistered forecast test central and presenting the power and coverage result as a qualified lesson from this case. The paper already did this. The following wording was tightened:

- **Abstract.** The power statement now says it comes from simulations across repeated samples. The 6% is "this sample" and the range is "for this sample". "Standard methods overstated…" now names the methods tested and calls the result a case study: "a standard Gaussian power simulation overstated the test′s sensitivity, and the moving-block bootstrap intervals were too narrow".
- **§1.** The first use of "four-quarter-ahead" points to the horizon convention in Box 1.
- **§7, episode.** "One episode dominates the record" is replaced: most of the predictor′s variation came during the 2008–09 crisis, and most of the GDP forecast loss came from forecasts of the recovery that followed. The power figure is described as a repeated-sample simulation result.
- **§7, lessons.** The turning-point lesson is now framed as a hypothesis for a future preregistered test, about downside risk and linked to extension 2. The methods lesson is stated in the past tense for this design.

The protected passages and tables were rechecked by script. No result changed.

Entry 58 (22 Oct 2026): four precision edits from reader feedback (results seen)

- **The 6%–44% range.** It is now labelled in the abstract as "a post-lock sensitivity interval, calibrated by simulation", so it is not mistaken for the preregistered interval. Later mentions of the 6% in the abstract and §7 refer to the sensitivity interval.
- **Horizon.** §1 and Box 1 now use one wording: the target is quarter o + 4, four quarters after the origin quarter o. Box 1 adds that GDP is observed only through o − 1.
- **SPF comparison.** The abstract now says that adding a credit correction to professional forecasters' median GDP forecast made it 2.5% worse; unemployment forecasts were 1.1% worse. This replaces "1–3% worse". §1 finding 1 now says "credit-corrected median SPF forecast".
- **Contributions paragraph in §1.** It now names the methods tested and their scope: the Gaussian-path power simulation overstated power, and in simulations on the realised predictor path the chosen moving-block bootstrap intervals undercovered.

The protected passages and tables were rechecked by script. No result changed.
